Anova

Anova Tables for Various Statistical Models

Description

Calculates type-II or type-III analysis-of-variance tables for model objects produced by lm, glm, multinom (in the **nnet** package), polr (in the **MASS** package), coxph (in the **survival** package), coxme (in the **coxme** pckage), svyglm (in the **survey** package), rlm (in the **MASS** package), lmer in the **lme4** package, lme in the **nlme** package, and (by the default method) for most models with a linear predictor and asymptotically normal coefficients (see details below). For linear models, F-tests are calculated; for generalized linear models, likelihood-ratio chisquare, or F-tests are calculated; for multinomial logit and proportional-odds logit models, likelihood-ratio tests are calculated. Various test statistics are provided for multivariate linear models produced by lm or manova. Partial-likelihood-ratio tests or Wald tests are provided for Cox models. Wald chi-square tests are provided for fixed effects in linear and generalized linear mixed-effects models. Wald chi-square or F tests are provided in the default case.

Usage

```
Anova(mod, ...)
Manova(mod, ...)
## S3 method for class 'lm'
Anova(mod, error, type=c("II", "III", 2, 3),
white.adjust=c(FALSE, TRUE, "hc3", "hc0", "hc1", "hc2", "hc4"),
vcov.=NULL, singular.ok, ...)
## S3 method for class 'aov'
Anova(mod, ...)
## S3 method for class 'glm'
Anova(mod, type=c("II","III", 2, 3),
    test.statistic=c("LR", "Wald", "F"),
    error, error.estimate=c("pearson", "dispersion", "deviance"),
   vcov.=vcov(mod, complete=TRUE), singular.ok, ...)
## S3 method for class 'multinom'
Anova(mod, type = c("II","III", 2, 3), ...)
## S3 method for class 'polr'
Anova(mod, type = c("II","III", 2, 3), \ldots)
## S3 method for class 'mlm'
Anova(mod, type=c("II", "III", 2, 3), SSPE, error.df,
    idata, idesign, icontrasts=c("contr.sum", "contr.poly"), imatrix,
    test.statistic=c("Pillai", "Wilks", "Hotelling-Lawley", "Roy"),...)
```

```
## S3 method for class 'manova'
Anova(mod, ...)
## S3 method for class 'mlm'
Manova(mod, ...)
## S3 method for class 'Anova.mlm'
print(x, ...)
## S3 method for class 'Anova.mlm'
summary(object, test.statistic, univariate=object$repeated,
    multivariate=TRUE, p.adjust.method, ...)
## S3 method for class 'summary.Anova.mlm'
print(x, digits = getOption("digits"),
    SSP=TRUE, SSPE=SSP, ...)
## S3 method for class 'univaov'
print(x, digits = max(getOption("digits") - 2L, 3L),
                          style=c("wide", "long"),
                          by=c("response", "term"),
## S3 method for class 'univaov'
as.data.frame(x, row.names, optional, by=c("response", "term"), ...)
## S3 method for class 'coxph'
Anova(mod, type=c("II", "III", 2, 3),
test.statistic=c("LR", "Wald"), ...)
## S3 method for class 'coxme'
Anova(mod, type=c("II", "III", 2, 3),
    test.statistic=c("Wald", "LR"), ...)
## S3 method for class 'lme'
Anova(mod, type=c("II", "III", 2, 3),
vcov.=vcov(mod, complete=FALSE), singular.ok, ...)
## S3 method for class 'mer'
Anova(mod, type=c("II", "III", 2, 3),
test.statistic=c("Chisq", "F"), vcov.=vcov(mod, complete=FALSE), singular.ok, ...)
## S3 method for class 'merMod'
Anova(mod, type=c("II", "III", 2, 3),
  test.statistic=c("Chisq", "F"), vcov.=vcov(mod, complete=FALSE), singular.ok, ...)
## S3 method for class 'svyglm'
```

```
Anova(mod, ...)
## S3 method for class 'rlm'
Anova(mod, ...)
## Default S3 method:
Anova(mod, type=c("II", "III", 2, 3),
test.statistic=c("Chisq", "F"), vcov.=vcov(mod, complete=FALSE),
singular.ok, ...)
```

Arguments

mod lm, aov, glm, multinom, polr mlm, coxph, coxme, lme, mer, merMod, svyglm,

rlm, or other suitable model object.

for a linear model, an 1m model object from which the error sum of squares error

and degrees of freedom are to be calculated. For F-tests for a generalized linear model, a glm object from which the dispersion is to be estimated. If not

specified, mod is used.

type of test, "II", "III", 2, or 3. Roman numerals are equivalent to the corretype

sponding Arabic numerals.

singular.ok defaults to TRUE for type-II tests, and FALSE for type-III tests where the tests for

models with aliased coefficients will not be straightforwardly interpretable; if

FALSE, a model with aliased coefficients produces an error.

test.statistic for a generalized linear model, whether to calculate "LR" (likelihood-ratio),

"Wald", or "F" tests; for a Cox or Cox mixed-effects model, whether to calculate "LR" (partial-likelihood ratio) or "Wald" tests; in the default case or for linear mixed models fit by 1mer, whether to calculate Wald "Chisq" or Kenward-Roger "F" tests with Satterthwaite degrees of freedom (warning: the KR F-tests can be very time-consuming). For a multivariate linear model, the multivariate test statistic to compute — one of "Pillai", "Wilks", "Hotelling-Lawley", or "Roy", with "Pillai" as the default. The summary method for Anova.mlm objects permits the specification of more than one multivariate test statistic, and

the default is to report all four.

error.estimate for F-tests for a generalized linear model, base the dispersion estimate on the

Pearson residuals ("pearson", the default); use the dispersion estimate in the model object ("dispersion"); or base the dispersion estimate on the residual deviance ("deviance"). For binomial or Poisson GLMs, where the dispersion is fixed to 1, setting error. estimate="dispersion" is changed to "pearson",

with a warning.

white.adjust if not FALSE, the default, tests use a heteroscedasticity-corrected coefficient covariance matrix; the various values of the argument specify different corrections.

See the documentation for hccm for details. If white.adjust=TRUE then the

"hc3" correction is selected.

For Anova for a multivariate linear model, the error sum-of-squares-and-products

matrix; if missing, will be computed from the residuals of the model; for the print method for the summary of an Anova of a multivariate linear model,

whether or not to print the error SSP matrix (defaults to TRUE).

SSPE

SSP if TRUE (the default), print the sum-of-squares and cross-products matrix for the

hypothesis and the response-transformation matrix.

error.df The degrees of freedom for error; if missing, will be taken from the model.

idata an optional data frame giving a factor or factors defining the intra-subject model

for multivariate repeated-measures data. See *Details* for an explanation of the intra-subject design and for further explanation of the other arguments relating

to intra-subject factors.

idesign a one-sided model formula using the "data" in idata and specifying the intra-

subject design.

icontrasts names of contrast-generating functions to be applied by default to factors and

> ordered factors, respectively, in the within-subject "data"; the contrasts must produce an intra-subject model matrix in which different terms are orthogonal.

The default is c("contr.sum", "contr.poly").

imatrix as an alternative to specifying idata, idesign, and (optionally) icontrasts,

the model matrix for the within-subject design can be given directly in the form of list of named elements. Each element gives the columns of the within-subject model matrix for a term to be tested, and must have as many rows as there are responses; the columns of the within-subject model matrix for different terms

must be mutually orthogonal.

x, object object of class "Anova.mlm" to print or summarize.

multivariate, univariate

compute and print multivariate and univariate tests for a repeated-measures ANOVA or multivariate linear model; the default is TRUE for both for repeated measures and TRUE for multivariate for a multivariate linear model.

p.adjust.method

if given for a multivariate linear model when univariate tests are requested, the univariate tests are corrected for simultaneous inference by term; if specified, should be one of the methods recognized by p.adjust or TRUE, in which case

the default (Holm) adjustment is used.

digits minimum number of significant digits to print.

for printing univariate tests if requested for a multivariate linear model; one of style

"wide", the default, or "long".

if univariate tests are printed in "long" style, they can be ordered by "response", by

the default, or by "term".

row.names, optional

not used.

in the default method, an optional coefficient-covariance matrix or function vcov.

> to compute a covariance matrix, computed by default by applying the generic vcov function to the model object. A similar argument may be supplied to the 1m method, and the default (NULL) is to ignore the argument; if both vcov. and white.adjust are supplied to the 1m method, the latter is used. In the glm method, vcov. is ignored unless test="Wald"; in the mer and merMod methods,

vcov. is ignored if test="F".

do not use.

Details

The designations "type-II" and "type-III" are borrowed from SAS, but the definitions used here do not correspond precisely to those employed by SAS. Type-II tests are calculated according to the principle of marginality, testing each term after all others, except ignoring the term's higher-order relatives; so-called type-III tests violate marginality, testing each term in the model after all of the others. This definition of Type-II tests corresponds to the tests produced by SAS for analysis-of-variance models, where all of the predictors are factors, but not more generally (i.e., when there are quantitative predictors). Be very careful in formulating the model for type-III tests, or the hypotheses tested will not make sense.

As implemented here, type-II Wald tests are a generalization of the linear hypotheses used to generate these tests in linear models.

For tests for linear models, multivariate linear models, and Wald tests for generalized linear models, Cox models, mixed-effects models, generalized linear models fit to survey data, and in the default case, Anova finds the test statistics without refitting the model. The svyglm method simply calls the default method and therefore can take the same arguments.

The standard R anova function calculates sequential ("type-I") tests. These rarely test interesting hypotheses in unbalanced designs.

A MANOVA for a multivariate linear model (i.e., an object of class "mlm" or "manova") can optionally include an intra-subject repeated-measures design. If the intra-subject design is absent (the default), the multivariate tests concern all of the response variables. To specify a repeated-measures design, a data frame is provided defining the repeated-measures factor or factors via idata, with default contrasts given by the icontrasts argument. An intra-subject model-matrix is generated from the formula specified by the idesign argument; columns of the model matrix corresponding to different terms in the intra-subject model must be orthogonal (as is insured by the default contrasts). Note that the contrasts given in icontrasts can be overridden by assigning specific contrasts to the factors in idata. As an alternative, the within-subjects model matrix can be specified directly via the imatrix argument. Manova is essentially a synonym for Anova for multivariate linear models.

If univariate tests are requested for the summary of a multivariate linear model, the object returned contains a univaov component of "univaov"; print and as.data.frame methods are provided for the "univaov" class.

For the default method to work, the model object must contain a standard terms element, and must respond to the vcov, coef, and model.matrix functions. If any of these requirements is missing, then it may be possible to supply it reasonably simply (e.g., by writing a missing vcov method for the class of the model object).

Value

An object of class "anova", or "Anova.mlm", which usually is printed. For objects of class "Anova.mlm", there is also a summary method, which provides much more detail than the print method about the MANOVA, including traditional mixed-model univariate F-tests with Greenhouse-Geisser and Huynh-Feldt corrections.

Warning

Be careful of type-III tests: For a traditional multifactor ANOVA model with interactions, for example, these tests will normally only be sensible when using contrasts that, for different terms, are

orthogonal in the row-basis of the model, such as those produced by contr.sum, contr.poly, or contr.helmert, but not by the default contr.treatment. In a model that contains factors, numeric covariates, and interactions, main-effect tests for factors will be for differences over the origin. In contrast (pun intended), type-II tests are invariant with respect to (full-rank) contrast coding. If you don't understand this issue, then you probably shouldn't use Anova for type-III tests.

Author(s)

John Fox < jfox@mcmaster.ca>; the code for the Mauchly test and Greenhouse-Geisser and Huynh-Feldt corrections for non-spericity in repeated-measures ANOVA are adapted from the functions stats:::stats:::mauchly.test.SSD and stats:::sphericity by R Core; summary.Anova.mlm and print.summary.Anova.mlm incorporates code contributed by Gabriel Baud-Bovy.

avPlots 11

avPlots

Added-Variable Plots

Description

These functions construct added-variable, also called partial-regression, plots for linear and generalized linear models.

Usage

```
avPlots(model, ...)
## Default S3 method:
avPlots(model, terms=~., intercept=FALSE,
  layout=NULL, ask, main, ...)
avp(...)
avPlot(model, ...)
## S3 method for class 'lm'
avPlot(model, variable,
id=TRUE, col = carPalette()[1], col.lines = carPalette()[2],
xlab, ylab, pch = 1, lwd = 2, cex = par("cex"), pt.wts = FALSE,
main=paste("Added-Variable Plot:", variable),
grid=TRUE,
ellipse=FALSE,
 marginal.scale=FALSE, ...)
## S3 method for class 'glm'
avPlot(model, variable,
id=TRUE,
col = carPalette()[1], col.lines = carPalette()[2],
xlab, ylab, pch = 1, lwd = 2, cex = par("cex"), pt.wts = FALSE,
type=c("Wang", "Weisberg"),
main=paste("Added-Variable Plot:", variable), grid=TRUE,
ellipse=FALSE, ...)
```

Arguments

model model object produced by 1m or g1m.

terms A one-sided formula that specifies a subset of the predictors. One added-variable

plot is drawn for each term. For example, the specification terms = \sim .-X3 would plot against all terms except for X3. If this argument is a quoted name of one of

the terms, the added-variable plot is drawn for that term only.

intercept Include the intercept in the plots; default is FALSE.

12 avPlots

variable A quoted string giving the name of a regressor in the model matrix for the hori-

zontal axis.

layout If set to a value like c(1,1) or c(4,3), the layout of the graph will have this

many rows and columns. If not set, the program will select an appropriate layout. If the number of graphs exceed nine, you must select the layout yourself, or you will get a maximum of nine per page. If layout=NA, the function does not set the layout and the user can use the par function to control the layout, for example

to have plots from two models in the same graphics window.

main The title of the plot; if missing, one will be supplied.

ask If TRUE, ask the user before drawing the next plot; if FALSE don't ask.

... avPlots passes these arguments to avPlot. avPlot passes them to plot.

controls point identification; if FALSE, no points are identified; can be a list of

named arguments to the showLabels function; TRUE, the default, is equivalent to

list(method=list(abs(residuals(model,type="pearson")), "x"), n=2, cex=1, col=carPalette(

which identifies the 2 points with the largest residuals and the 2 points with the

most extreme horizontal values (i.e., largest partial leverage).

col color for points; the default is the *second* entry in the current **car** palette (see

carPalette and par).

col.lines color for the fitted line.

pch plotting character for points; default is 1 (a circle, see par).

lwd line width; default is 2 (see par).

cex size of plotted points; default is taken from par ("cex").

pt.wts if TRUE (the default is FALSE), for a weighted least squares fit or a generalized

linear model, the areas of plotted points are made proportional to the weights,

with the average size taken from the cex argument.

xlab x-axis label. If omitted a label will be constructed. ylab y-axis label. If omitted a label will be constructed.

type if "Wang" use the method of Wang (1985); if "Weisberg" use the method in the

Arc software associated with Cook and Weisberg (1999).

grid If TRUE, the default, a light-gray background grid is put on the graph.

ellipse controls plotting data-concentration ellipses. If FALSE (the default), no ellipses

are plotted. Can be a list of named values giving levels, a vector of one or more bivariate-normal probability-contour levels at which to plot the ellipses; and robust, a logical value determing whether to use the cov. trob function in the MASS package to calculate the center and covariance matrix for the data

ellipses. TRUE is equivalent to list(levels=c(.5,.95),robust=TRUE).

marginal.scale Consider an added-variable plot of Y versus X given Z. If this argument is FALSE

then the limits on the horizontal axis are determined by the range of the residuals from the regression of X on Z and the limits on the vertical axis are determined by the range of the residuals from the regressnio of Y on Z. If the argument is TRUE, then the limits on the horizontal axis are determined by the range of X minus it mean, and on the vertical axis by the range of Y minus its means; adjustment is made if necessary to include outliers. This scaling allows visualization of the correlations between Y and Z and between X and Z. For example, if the X and Z are highly correlated, then the points will be concentrated on the

middle of the plot.

avPlots 13

Details

The function intended for direct use is avPlots (for which avp is an abbreviation).

Value

These functions are used for their side effect id producing plots, but also invisibly return the coordinates of the plotted points.

Examples

```
avPlots(lm(prestige ~ income + education + type, data=Duncan))
avPlots(glm(partic != "not.work" ~ hincome + children,
    data=Womenlf, family=binomial), id=FALSE, pt.wts=TRUE)

m1 <- lm(partic ~ tfr + menwage + womwage + debt + parttime, Bfox)
par(mfrow=c(1,3))
# marginal plot, ignoring other predictors:
with(Bfox, dataEllipse(womwage, partic, levels=0.5))
abline(lm(partic ~ womwage, Bfox), col="red", lwd=2)
# AV plot, adjusting for others:
avPlots(m1, ~ womwage, ellipse=list(levels=0.5))
# AV plot, adjusting and scaling as in marginal plot
avPlots(m1, ~ womwage, marginal.scale=TRUE, ellipse=list(levels=0.5))</pre>
```

14 bcPower

bcPower Box-Cox, Box-Cox with Negatives Allowed, Yeo-Johnson and Basic Power Transformations

Description

Transform the elements of a vector or columns of a matrix using, the Box-Cox, Box-Cox with negatives allowed, Yeo-Johnson, or simple power transformations.

Usage

```
bcPower(U, lambda, jacobian.adjusted=FALSE, gamma=NULL)
bcnPower(U, lambda, jacobian.adjusted = FALSE, gamma)
bcnPowerInverse(z, lambda, gamma)
yjPower(U, lambda, jacobian.adjusted = FALSE)
basicPower(U,lambda, gamma=NULL)
```

Arguments

U A vector, matrix or data.frame of values to be transformed

lambda Power transformation parameter with one element for each column of U, usual-

lly in the range from -2 to 2.

jacobian.adjusted

If TRUE, the transformation is normalized to have Jacobian equal to one. The

default FALSE is almost always appropriate.

gamma For bcPower or basicPower, the transformation is of U + gamma, where gamma

is a positive number called a start that must be large enough so that U + gamma is strictly positive. For the bcnPower, Box-cox power with negatives allowed,

see the details below.

z a numeric vector the result of a call to bcnPower with jacobian.adjusted=FALSE.

Details

The Box-Cox family of scaled power transformations equals $(x^{\lambda} - 1)/\lambda$ for $\lambda \neq 0$, and $\log(x)$ if $\lambda = 0$. The bcPower function computes the scaled power transformation of $x = U + \gamma$, where γ is set by the user so $U + \gamma$ is strictly positive for these transformations to make sense.

The Box-Cox family with negatives allowed was proposed by Hawkins and Weisberg (2017). It is the Box-Cox power transformation of

$$z = .5(U + \sqrt{U^2 + \gamma^2})$$

where for this family γ is either user selected or is estimated. gamma must be positive if U includes negative values and non-negative otherwise, ensuring that z is always positive. The bcnPower

bcPower 15

transformations behave similarly to the bcPower transformations, and introduce less bias than is introduced by setting the parameter γ to be non-zero in the Box-Cox family.

The function bcnPowerInverse computes the inverse of the bcnPower function, so U = bcnPowerInverse(bcnPower(U, lamb is true for any permitted value of gam and lam.

If family="yeo.johnson" then the Yeo-Johnson transformations are used. This is the Box-Cox transformation of U+1 for nonnegative values, and of |U|+1 with parameter $2-\lambda$ for U negative.

The basic power transformation returns U^{λ} if λ is not 0, and $\log(\lambda)$ otherwise for U strictly positive.

If jacobian, adjusted is TRUE, then the scaled transformations are divided by the Jacobian, which is a function of the geometric mean of U for skewPower and yjPower and of U+gamma for bcPower. With this adjustment, the Jacobian of the transformation is always equal to 1. Jacobian adjustment facilitates computing the Box-Cox estimates of the transformation parameters.

Missing values are permitted, and return NA where ever U is equal to NA.

Value

Returns a vector or matrix of transformed values.

16 Boot

Boot

Bootstrapping for regression models

Description

This function provides a simple front-end to the boot function in the **boot** package that is tailored to bootstrapping based on regression models. Whereas boot is very general and therefore has many arguments, the Boot function has very few arguments.

Usage

```
Boot(object, f=coef, labels=names(f(object)), R=999,
   method=c("case", "residual"), ncores=1, ...)

## Default S3 method:
Boot(object, f=coef, labels=names(f(object)),
   R=999, method=c("case", "residual"), ncores=1,
   start = FALSE, ...)

## S3 method for class 'lm'
Boot(object, f=coef, labels=names(f(object)),
   R=999, method=c("case", "residual"), ncores=1, ...)

## S3 method for class 'glm'
Boot(object, f=coef, labels=names(f(object)),
   R=999, method=c("case", "residual"), ncores=1, ...)

## S3 method for class 'nls'
Boot(object, f=coef, labels=names(f(object)),
   R=999, method=c("case", "residual"), ncores=1, ...)
```

Arguments

object	A regression object of class "lm", "glm" or "nls". The function may work with other regression objects that support the update method and have a subset argument. See discussion of the default method in the details below.
f	A function whose one argument is the name of a regression object that will be applied to the updated regression object to compute the statistics of interest. The default is coef, to return regression coefficient estimates. For example, f = function(obj) coef(obj)[1]/coef(obj)[2] will bootstrap the ratio of the first and second coefficient estimates.
labels	Provides labels for the statistics computed by f. Default labels are obtained from a call to f, or generic labels if f does not return names.
R	Number of bootstrap samples. The number of bootstrap samples actually computed may be smaller than this value if either the fitting method is iterative and

Boot 17

fails to converge for some boothstrap samples, or if the rank of a fitted model is different in a bootstrap replication than in the original data.

method The bootstrap method, either "case" for resampling cases or "residuals" for a

residual bootstrap. See the details below. The residual bootstrap is available

only for lm and nls objects and will return an error for glm objects.

... Arguments passed to the boot function, see boot.

start Should the estimates returned by f be passed as starting values for each bootstrap

iteration? Alternatively, start can be a numeric vector of starting values. The default is to use the estimates from the last bootstrap iteration as starting values

for the next iteration.

ncores A numeric argument that specifies the number of cores for parallel processing

for unix systems. If less than or equal to 1, no parallel processing will be used. Note in a Windows platform will produce a warning and set this argument to 1.

Details

Boot uses a regression object and the choice of method, and creates a function that is passed as the statistic argument to the boot function in the **boot** package. The argument R is also passed to boot. If ncores is greater than 1, then the parallel and ncpus arguments to boot are set appropriately to use multiple codes, if available, on your computer. All other arguments to boot are kept at their default values unless you pass values for them.

The methods available for lm and nls objects are "case" and "residual". The case bootstrap resamples from the joint distribution of the terms in the model and the response. The residual bootstrap fixes the fitted values from the original data, and creates bootstraps by adding a bootstrap sample of the residuals to the fitted values to get a bootstrap response. It is an implementation of Algorithm 6.3, page 271, of Davison and Hinkley (1997). For nls objects ordinary residuals are used in the resampling rather than the standardized residuals used in the lm method. The residual bootstrap for generalized linear models has several competing approaches, but none are without problems. If you want to do a residual bootstrap for a glm, you will need to write your own call to boot.

For the default object to work with other types of regression models, the model must have methods for the the following generic functions: residuals(object,type="pearson") must return Pearson residuals; fitted(object) must return fitted values; hatvalues(object) should return the leverages, or perhaps the value 1 which will effectively ignore setting the hatvalues. In addition, the data argument should contain no missing values among the columns actually used in fitting the model, as the resampling may incorrectly attempt to include cases with missing values. For lm, glm and nls, missing values cause the return of an error message.

An attempt to fit using a bootstrap sample may fail. In a lm or glm fit, the bootstrap sample could have a different rank from the original fit. In an nls fit, convergence may not be obtained for some bootstraps. In either case, NA are returned for the value of the function f. The summary methods handle the NAs appropriately.

Fox and Weisberg (2017) cited below discusses this function and provides more examples.

Value

See boot for the returned value of the structure returned by this function.

boxCox

Warning

C=A call like car::Boot(object,method="residual") will fail for the residual method if not preceded by library(car). If method="case" the library(car) command is not required.

Author(s)

Sanford Weisberg, <sandy@umn.edu>. Achim Zeileis added multicore support, and also fixed the default method to work for many more regression models.

See Also

Functions that work with boot objects from the **boot** package are boot.array, boot.ci, plot.boot and empinf. Additional functions in the **car** package are summary.boot, confint.boot, and hist.boot.

Examples

```
m1 <- lm(Fertility ~ ., swiss)
betahat.boot <- Boot(m1, R=199) # 199 bootstrap samples--too small to be useful
summary(betahat.boot) # default summary
confint(betahat.boot)
hist(betahat.boot)
# Bootstrap for the estimated residual standard deviation:
sigmahat.boot <- Boot(m1, R=199, f=sigmaHat, labels="sigmaHat")
summary(sigmahat.boot)
confint(sigmahat.boot)</pre>
```

boxCox

Graph the profile log-likelihood for Box-Cox transformations in 1D, or in 2D with the bcnPower family.

Description

Computes and optionally plots profile log-likelihoods for the parameter of the Box-Cox power family, the Yeo-Johnson power family, or for either of the parameters in a bcnPower family. This is a slight generalization of the boxcox function in the MASS package that allows for families of transformations other than the Box-Cox power family. the boxCox2d function produces a contour plot of the two-dimensional likelihood profile for the bcnPower family.

boxCox 19

Usage

```
boxCox(object, ...)
## Default S3 method:
boxCox(object,
        lambda = seq(-2, 2, 1/10), plotit = TRUE,
        interp = plotit, eps = 1/50,
        xlab=NULL, ylab=NULL, main= "Profile Log-likelihood",
        family="bcPower",
        param=c("lambda", "gamma"), gamma=NULL,
        grid=TRUE, ...)
## S3 method for class 'formula'
boxCox(object, lambda = seq(-2, 2, 1/10), plotit = TRUE, family = "bcPower",
    param = c("lambda", "gamma"), gamma = NULL, grid = TRUE,
    ...)
## S3 method for class 'lm'
boxCox(object, lambda = seq(-2, 2, 1/10), plotit = TRUE, ...)
boxCox2d(x, ksds = 4, levels = c(0.5, 0.95, 0.99, 0.999),
                 main = "bcnPower Log-likelihood", grid=TRUE, ...)
```

Arguments

object	a formula or fitted model object of class 1m or aov.

lambda vector of values of λ , with default (-2, 2) in steps of 0.1, where the profile log-

likelihood will be evaluated.

plotit logical which controls whether the result should be plotted; default TRUE.

interp logical which controls whether spline interpolation is used. Default to TRUE if

plotting with lambda of length less than 100.

eps Tolerance for lambda = 0; defaults to 0.02.

xlab defaults to "lambda" or "gamma".

ylab defaults to "log-Likelihood" or for bcnPower family to the appropriate label.

family Defaults to "bcPower" for the Box-Cox power family of transformations. If set to "yjPower" the Yeo-Johnson family, which permits negative responses, is

used. If set to bcnPower the function gives the profile log-likelihood for the

parameter selected via param.

param Relevant only to family="bcnPower", produces a profile log-likelihood for the

parameter selected, maximizing over the remaining parameter.

gamma For use when the family="bcnPower",param="gamma". If this is a vector of

positive values, then the profile log-likelihood for the location (or start) parameter in the bcnPower family is evaluated at these values of gamma. If gamma is NULL, then evaulation is done at 100 equally spaced points between

boxCox

	min(.01, gmax -3*sd) and gmax + 3*sd, where gmax is the maximimum likelihood estimate of gamma, and sd is the sd of the response. See bcnPower for the definition of gamma.
grid	If TRUE, the default, a light-gray background grid is put on the graph.
	additional arguments passed to plot, or to contour with boxCox2d.
x	An object created by a call to powerTransform using family="bcnPower".
ksds	Contour plotting of the log-likelihood surface will cover plus of minus ksds standard deviations on each axis.
levels	Contours will be drawn at the values of levels. For example, levels=c(.5,.99) would display two contours, at the 50% level and at the 99% level.
main	Title for the contour plot or the profile log-likelihood plot

Details

The boxCox function is an elaboration of the boxcox function in the MASS package. The first 7 arguments are the same as in boxcox, and if the argument family="bcPower" is used, the result is essentially identical to the function in MASS. Two additional families are the yjPower and bcnPower families that allow a few values of the response to be non-positive. The bcnPower family has two parameters: a power λ and a start or location parameter γ , and the boxCox function can be used to obtain a profile log-likelihood for either parameter with λ as the default. Alternatively, the boxCox2d function can be used to get a contour plot of the profile log-likelihood.

Value

Both functions are designed for their side effects of drawing a graph. The boxCox function returns a list of the lambda (or possibly, gamma) vector and the computed profile log-likelihood vector, invisibly if the result is plotted. If plotit=TRUE plots log-likelihood vs lambda and indicates a 95% confidence interval about the maximum observed value of lambda. If interp=TRUE, spline interpolation is used to give a smoother plot.

Examples

boxCoxVariable

Constructed Variable for Box-Cox Transformation

Description

Computes a constructed variable for the Box-Cox transformation of the response variable in a linear model.

Usage

```
boxCoxVariable(y)
```

Arguments

У

response variable.

Details

The constructed variable is defined as $y[\log(y/\tilde{y}) - 1]$, where \tilde{y} is the geometric mean of y.

The constructed variable is meant to be added to the right-hand-side of the linear model. The t-test for the coefficient of the constructed variable is an approximate score test for whether a transformation is required.

If b is the coefficient of the constructed variable, then an estimate of the normalizing power transformation based on the score statistic is 1-b. An added-variable plot for the constructed variable shows leverage and influence on the decision to transform y.

Value

a numeric vector of the same length as y.

Boxplot

Boxplots With Point Identification

Description

Boxplot is a wrapper for the standard R boxplot function, providing point identification, axis labels, and a formula interface for boxplots without a grouping variable.

Usage

```
Boxplot(y, ...)
## Default S3 method:
Boxplot(y, g, id=TRUE, xlab, ylab, ...)
## S3 method for class 'formula'
Boxplot(formula, data=NULL, subset, na.action=NULL, id=TRUE, xlab, ylab, ...)
## S3 method for class 'list'
Boxplot(y, xlab="", ylab="", ...)
## S3 method for class 'data.frame'
Boxplot(y, id=TRUE, ...)
## S3 method for class 'matrix'
Boxplot(y, ...)
```

Boxplot 23

Arguments

id

y a numeric variable for which the boxplot is to be constructed; a list of numeric variables, each element of which will be treated as a group; a numeric data frame or a numeric matrix, each of whose columns will be treated as a group.

g a grouping variable, usually a factor, for constructing parallel boxplots.

a list of named elements giving one or more specifications for labels of individual points ("outliers"): n, the maximum number of points to label (default 10); location, "lr" (left or right) of points or "avoid" to try to avoid overplotting; method, one of "y" (automatic, the default), "identify" (interactive), or "none"; col for labels (default is the first color in carPalette()); and cex

size of labels (default is 1). Can be FALSE to suppress point identification or TRUE (the default) to use all defaults. This is similar to how showLabels handles point labels for other functions in the **car** package, except that the usual

default is id=FALSE.

xlab, ylab text labels for the horizontal and vertical axes; if missing, Boxplot will use the

variable names, or, in the case of a list, data frame, or matrix, empty labels.

formula a 'model' formula, of the form ~ y to produce a boxplot for the variable y, or of

the form $y \sim g, y \sim g1*g2*...,$ or $y \sim g1 + g2 + ...$ to produce parallel boxplots

for y within levels of the grouping variable(s) g, etc., usually factors.

data, subset, na.action

as for statistical modeling functions (see, e.g., 1m).

... further arguments, such as at, to be passed to boxplot.

Author(s)

John Fox < jfox@mcmaster.ca>, with a contribution from Steve Ellison to handle at argument (see boxplot).

References

Fox, J. and Weisberg, S. (2019) An R Companion to Applied Regression, Third Edition, Sage.

Boxplot(income ~ type, data=Prestige)
Boxplot(income ~ type, data=Prestige, at=c(1, 3, 2))
Boxplot(k5 + k618 ~ lfp*wc, data=Mroz)
with(Prestige, Boxplot(income, id=list(labels=rownames(Prestige))))
with(Prestige, Boxplot(income, type, id=list(labels=rownames(Prestige))))
Boxplot(scale(Prestige[, 1:4]))
```

24 boxTidwell

Description

Computes the Box-Tidwell power transformations of the predictors in a linear model.

Usage

```
boxTidwell(y, ...)
## S3 method for class 'formula'
boxTidwell(formula, other.x=NULL, data=NULL, subset,
    na.action=getOption("na.action"), verbose=FALSE, tol=0.001,
    max.iter=25, ...)
## Default S3 method:
boxTidwell(y, x1, x2=NULL, max.iter=25, tol=0.001,
    verbose=FALSE, ...)
## S3 method for class 'boxTidwell'
print(x, digits=getOption("digits") - 2, ...)
```

Arguments

formula	two-sided formula, the right-hand-side of which gives the predictors to be transformed.
other.x	one-sided formula giving the predictors that are <i>not</i> candidates for transformation, including (e.g.) factors.
data	an optional data frame containing the variables in the model. By default the variables are taken from the environment from which boxTidwell is called.
subset	an optional vector specifying a subset of observations to be used.
na.action	a function that indicates what should happen when the data contain NAs. The default is set by the na.action setting of options.
verbose	if TRUE a record of iterations is printed; default is FALSE.
tol	if the maximum relative change in coefficients is less than tol then convergence is declared.
max.iter	maximum number of iterations.
У	response variable.
x1	matrix of predictors to transform.
x2	matrix of predictors that are <i>not</i> candidates for transformation.
	not for the user.
X	boxTidwell object.
digits	number of digits for rounding.

brief 25

Details

The maximum-likelihood estimates of the transformation parameters are computed by Box and Tidwell's (1962) method, which is usually more efficient than using a general nonlinear least-squares routine for this problem. Score tests for the transformations are also reported.

Value

an object of class boxTidwell, which is normally just printed.

## S3 method for class 'polr'
brief(object, terms = ~ .,
    intercept, pvalues=FALSE,
    digits=3, horizontal=TRUE, exponentiate=TRUE, ...)
## Default S3 method:
brief(object, terms = ~ .,
    intercept=missing(terms), pvalues=FALSE,
    digits=3, horizontal=TRUE, ...)
```

Arguments

object a data or model object to abbreviate.

rows for a matrix or data frame, a 2-element integer vector with the number of rows to

print at the beginning and end of the display; for a vector or factor, the number of lines of output to show at the beginning and end; for a list, the number of elements to show at the beginning and end; for a function, the number of lines

to show at the beginning and end.

cols for a matrix or data frame, a 2-element integer vector with the number of columns

to print at the beginning (i.e., left) and end (right) of the display.

head, tail alternatives to the rows argument; if TRUE, print the first or last 6 rows; can also

brief 27

be the number of the first or last few rows to print; only one of heads and tails

should be specified; ignored if FALSE (the default).

elided controls whether to report the number of elided elements, rows, or columns;

default is TRUE.

classes show the class of each column of a data frame at the top of the column; the

classes are shown in single-character abbreviated form—e.g., [f] for a factor, [i] for an integer variable, [n] for a numeric variable, [c] for a character vari-

able.

terms a one-sided formula giving the terms to summarize; the default is ~ .—i.e., to

summarize all terms in the model.

intercept whether or not to include the intercept; the default is TRUE unless the terms

argument is given, in which case the default is FALSE; ignored for polr models.

pvalues include the p-value for each coefficient in the table; default is FALSE.

exponentiate for a "glm" or "glmerMod" model using the log or logit link, or a "polr"

or "multinom" model, show exponentiated coefficient estimates and confidence

bounds.

digits significant digits for printing.

horizontal if TRUE (the default), orient the summary produced by brief horizontally, which

typically saves space.

dispersion use an estimated covariance matrix computed as the dispersion times the un-

scaled covariance matrix; see summary.glm

vcov. either a matrix giving the estimated covariance matrix of the estimates, or a

function that when called with object as an argument returns an estimated covariance matrix of the estimates. If not set, vcov(object,complete=FALSE) is called to use the usual estimated covariance matrix with aliased regressors removed. Other choices include the functions documented at hccm, and a bootstrap estimate vcov.=vcov(Boot(object)); see the documentation for Boot. NOTES: (1) The dispersion and vcov. arguments may not *both* be specified. (2) Setting vcov.=vcov returns an error if the model includes aliased terms; use vcov.=vcov(object,complete=FALSE). (3) The hccm method will generally return a matrix of full rank even if the model has aliased terms. Similarly

vcov.=vcov(Boot(object)) may return a full rank matrix.

... arguments to pass down.

Value

Invisibly returns object for a data object, or summary for a model object.

Note

The method brief.matrix calls brief.data.frame, and brief.tbl (for tibbles) calls print.

box.cox.powers is replaced by powerTransform.
box.cox.var is replaced by boxCoxVariable.
box.tidwell is replaced by boxTidwell.
cookd is replaced by cooks. distance in the stats package.
confidence.ellipse is replaced by confidenceEllipse.
ceres.plot and ceres.plots are now replaced by the ceresPlot and ceresPlots functions.
cr.plot and cr.plots are now replaced by the crPlot and crPlots functions.
data.ellipse is replaced by dataEllipse.
durbin.watson is replaced by durbinWatsonTest.
levene.test is replaced by leveneTest function.
leverage.plot and leverage.plots are now replaced by the leveragePlot and leveragePlots
functions.
linear.hypothesis is replaced by the linearHypothesis function.
ncv.test is replaced by ncvTest.
outlier.test is replaced by outlierTest.
qq.plot is replaced by qqPlot.
skewPower is replaced by bcnPower.
spread.level.plot is replaced by spreadLevelPlot.

30 car-internal.Rd

car-deprecated

Deprecated Functions in the car Package

Description

These functions are provided for compatibility with older versions of the **car** package only, and may be removed eventually. Commands that worked in versions of the **car** package prior to version 3.0-0 will not necessarily work in version 3.0-0 and beyond, or may not work in the same manner.

Usage

```
bootCase(...)
nextBoot(...)
```

Arguments

... arguments to pass to methods.

Details

These functions are replaced by Boot.

See Also

See Also Boot

car-internal.Rd

Internal Objects for the car package

Description

These objects (currently only the .carEnv environment) are exported for technical reasons and are not for direct use.

Author(s)

John Fox <jfox@mcmaster.ca>

carHexsticker 31

carHexsticker

View the Official Hex Sticker for the car Package

Description

Open the official hex sticker for the car package in your browser

Usage

```
carHexsticker()
```

Value

Used for its side effect of openning the hex sticker for the car package in your browser.

Author(s)

```
John Fox <jfox@mcmaster.ca>
```

Examples

```
## Not run:
carHexsticker()
## End(Not run)
```

carPalette

Set or Retrieve car Package Color Palette

Description

This function is used to set or retrieve colors to be used in **car** package graphics functions.

Usage

```
carPalette(palette)
```

Arguments

palette

if missing, returns the colors that will be used in **car** graphics; if present, the colors to be used in graphics will be set. The palette argument may also be one of "car" or "default" to use the default **car** palette (defined below), "R" to use the default R palette, or "colorblind" to use a colorblind-friendly palette (from https://jfly.uni-koeln.de/color/).

32 carWeb

Details

This function sets or returns the value of options(carPalette=pallete) that will be use in **car** graphics functions to determine colors. The default is c("black", "blue", "magenta", "cyan", "orange", "gray", "greens which is nearly a permutation of the colors returned by the standard palette function that minimizes the use of red and green in the same graph, and that substitutes orange for the often hard to see yellow.

Value

Invisibly returns the previous value of the car palette.

Author(s)

Sanford Weisberg and John Fox

References

Fox, J. and Weisberg, S. (2019) An R Companion to Applied Regression, Third Edition, Sage.

See Also

```
palette, colors
```

Examples

```
# Standard color palette
palette()
# car standard color palette
carPalette()
# set colors to all black
carPalette(rep("black", 8))
# Use a custom color palette with 12 distinct colors
carPalette(sample(colors(distinct=TRUE), 12))
# restore default
carPalette("default")
```

carWeb

Access to the R Companion to Applied Regression Website

Description

This function will access the website for An R Companion to Applied Regression, or setup files or data.

Usage

```
carWeb(page = c("webpage", "errata", "taskviews"), script, data, setup)
```

ceresPlots 33

Arguments

page	A character string indicating what page to open. The default "webpage" will open the main web page, "errata" displays the errata sheet for the book, "taskviews" fetches and displays a list of available task views from CRAN.
script	The quoted name of a chapter in <i>An R Companion to Applied Regression</i> , like "chap-1", "chap-2", up to "chap-10". All the R commands used in that chapter will be displayed in your browser, where you can save them as a text file.
data	The quoted name of a data file in <i>An R Companion to Applied Regression</i> , like "Duncan.txt" or "Prestige.txt". The file will be opened in your web browser. You do not need to specify the extension .txt
setup	If TRUE this command will download a number of files to your computer that are discussed in Fox and Weisberg (2019), beginning in Chapter 1.

Value

Either displays a web page or a PDF document or downloads files to your working directory.

Author(s)

Sanford Weisberg, based on the function UsingR in the UsingR package by John Verzani

References

Fox, J. and Weisberg, S. (2019) An R Companion to Applied Regression, Third Edition, Sage.

Examples

```
## Not run:
carWeb()
carWeb(setup=TRUE)
## End(Not run)
```

ceresPlots	Ceres Plots
------------	-------------

Description

These functions draw Ceres plots for linear and generalized linear models.

34 ceresPlots

Usage

Arguments

model	model object	produced by	lmorglm
mouci	model object	produced by	TIII OI STIII.

terms A one-sided formula that specifies a subset of the regressors. One componentplus-residual plot is drawn for each term. The default ~. is to plot against all

numeric predictors. For example, the specification terms = ~ . -X3 would plot against all predictors except for X3. Factors and nonstandard predictors such as B-splines are skipped. If this argument is a quoted name of one of the regressors,

the component-plus-residual plot is drawn for that predictor only.

layout If set to a value like c(1,1) or c(4,3), the layout of the graph will have this

many rows and columns. If not set, the program will select an appropriate layout. If the number of graphs exceed nine, you must select the layout yourself, or you will get a maximum of nine per page. If layout=NA, the function does not set the layout and the user can use the par function to control the layout, for example

to have plots from two models in the same graphics window.

ask If TRUE, ask the user before drawing the next plot; if FALSE, the default, don't

ask. This is relevant only if not all the graphs can be drawn in one window.

main Overall title for any array of cerers plots; if missing a default is provided.

... ceresPlots passes these arguments to ceresPlot. ceresPlot passes them to

plot.

variable A quoted string giving the name of a variable for the horizontal axis

id controls point identification; if FALSE (the default), no points are identified; can

be a list of named arguments to the showLabels function; TRUE is equivalent to

list(method=list(abs(residuals(model,type="pearson")),"x"),n=2,cex=1,col=carPalette

which identifies the 2 points with the largest residuals and the 2 points with the

most extreme horizontal (X) values.

line TRUE to plot least-squares line.

smooth specifies the smoother to be used along with its arguments; if FALSE, no smoother

is shown; can be a list giving the smoother function and its named arguments;

ceresPlots 35

	TRUE, the default, is equivalent to list(smoother=loessLine). See ScatterplotSmoothers for the smoothers supplied by the car package and their arguments. Ceres plots do not support variance smooths.
col	color for points; the default is the first entry in the current car palette (see carPalette and par).
col.lines	a list of at least two colors. The first color is used for the ls line and the second color is used for the fitted lowess line. To use the same color for both, use, for example, col.lines=c("red", "red")
xlab,ylab	labels for the x and y axes, respectively. If not set appropriate labels are created by the function.
pch	plotting character for points; default is 1 (a circle, see par).
lwd	line width; default is 2 (see par).
grid	If TRUE, the default, a light-gray background grid is put on the graph

Details

Ceres plots are a generalization of component+residual (partial residual) plots that are less prone to leakage of nonlinearity among the predictors.

The function intended for direct use is ceresPlots.

The model cannot contain interactions, but can contain factors. Factors may be present in the model, but Ceres plots cannot be drawn for them.

Value

NULL. These functions are used for their side effect: producing plots.

```

36 compareCoefs

compareCoefs	Print estimated coefficients and their standard errors in a table for several regression models.

Description

This function extracts estimates of regression parameters and their standard errors from one or more models and prints them in a table.

Usage

```
compareCoefs(..., se = TRUE, zvals = FALSE, pvals = FALSE, vcov.,
    print = TRUE, digits = 3)
```

Arguments

	One or more regression-model objects. These may be of class lm, glm, nlm, or any other regression method for which the functions coef and vcov return appropriate values, or if the object inherits from the mer class created by the lme4 package or lme in the nlme package.
se	If TRUE, the default, show standard errors as well as estimates.
zvals	If TRUE (the default is FALSE), print Wald statistics, the ratio of each coefficient to its standard error.
pvals	If codeTRUE (the default is FALSE), print two-sided p-values from the standard normal distribution corresponding to the Wald statistics.
vcov.	an optional argument, specifying a function to be applied to all of the models, returning a coefficient covariance matrix for each, or a list with one element for each model, with each element either containing a function to be applied to the corresponding model or a coefficient covariance matrix for that model. If omitted, vcov is applied to each model. This argument can also be a list of estimated covariance matrices of the coefficient estimates.
print	If TRUE, the default, the results are printed in a nice format using printCoefmat. If FALSE, the results are returned as a matrix
digits	Passed to the printCoefmat function for printing the result.

Value

This function is mainly used for its side-effect of printing the result. It also invisibly returns a matrix of estimates, standard errors, Wald statistics, and p-values.

Contrasts 37

References

Fox, J. and Weisberg, S. (2019) An R Companion to Applied Regression, Third Edition, Sage.

Examples

```
mod1 <- lm(prestige ~ income + education, data=Duncan)
mod2 <- update(mod1, subset=-c(6,16))
mod3 <- update(mod1, . ~ . + type)
mod4 <- update(mod1, . ~ . + I(income + education)) # aliased coef.
compareCoefs(mod1)
compareCoefs(mod1, mod2, mod4)
compareCoefs(mod1, mod2, mod3, zvals=TRUE, pvals=TRUE)
compareCoefs(mod1, mod2, se=FALSE)
compareCoefs(mod1, mod1, vcov.=list(vcov, hccm))</pre>
```

Contrasts

Functions to Construct Contrasts

Description

These are substitutes for similarly named functions in the **stats** package (note the uppercase letter starting the second word in each function name). The only difference is that the contrast functions from the **car** package produce easier-to-read names for the contrasts when they are used in statistical models.

The functions and this documentation are adapted from the **stats** package.

Usage

```
contr.Treatment(n, base = 1, contrasts = TRUE)
contr.Sum(n, contrasts = TRUE)
contr.Helmert(n, contrasts = TRUE)
```

Arguments

n a vector of levels for a factor, or the number of levels.

base an integer specifying which level is considered the baseline level. Ignored if

contrasts is FALSE.

contrasts a logical indicating whether contrasts should be computed.

Details

These functions are used for creating contrast matrices for use in fitting analysis of variance and regression models. The columns of the resulting matrices contain contrasts which can be used for coding a factor with n levels. The returned value contains the computed contrasts. If the argument contrasts is FALSE then a square matrix is returned.

Several aspects of these contrast functions are controlled by options set via the options command:

38 Contrasts

decorate.contrasts This option should be set to a 2-element character vector containing the prefix and suffix characters to surround contrast names. If the option is not set, then c("[","]") is used. For example, setting options(decorate.contrasts=c(".","")) produces contrast names that are separated from factor names by a period. Setting options(decorate.contrasts=c("","")) reproduces the behaviour of the R base contrast functions.

decorate.contr.Treatment A character string to be appended to contrast names to signify treatment contrasts; if the option is unset, then "T." is used.

```
decorate.contr.Sum Similar to the above, with default "S.". decorate.contr.Helmert Similar to the above, with default "H.".
```

contr.Sum.show.levels Logical value: if TRUE (the default if unset), then level names are used for contrasts; if FALSE, then numbers are used, as in contr.sum in the base package.

Note that there is no replacement for contr.poly in the base package (which produces orthogonal-polynomial contrasts) since this function already constructs easy-to-read contrast names.

Value

A matrix with n rows and k columns, with k = n - 1 if contrasts is TRUE and k = n if contrasts is FALSE.

crPlots

Component+Residual (Partial Residual) Plots

Description

These functions construct component+residual plots, also called partial-residual plots, for linear and generalized linear models.

Usage

Arguments

model model object produced by 1m or g1m.

A one-sided formula that specifies a subset of the regressors. One componentplus-residual plot is drawn for each regressor. The default ~. is to plot against all numeric regressors. For example, the specification terms = ~ . -X3 would 40 crPlots

plot against all regressors except for X3, while terms = $\sim \log(X4)$ would give the plot for the predictor X4 that is represented in the model by $\log(X4)$. If this argument is a quoted name of one of the predictors, the component-plus-residual plot is drawn for that predictor only.

layout If set to a value like c(1,1) or c(4,3), the layout of the graph will have this

many rows and columns. If not set, the program will select an appropriate layout. If the number of graphs exceed nine, you must select the layout yourself, or you will get a maximum of nine per page. If layout=NA, the function does not set the layout and the user can use the par function to control the layout, for example

to have plots from two models in the same graphics window.

ask If TRUE, ask the user before drawing the next plot; if FALSE, the default, don't

ask. This is relevant only if not all the graphs can be drawn in one window.

main The title of the plot; if missing, one will be supplied.

... crPlots passes these arguments to crPlot. crPlot passes them to plot.

variable A quoted string giving the name of a variable for the horizontal axis.

id controls point identification; if FALSE (the default), no points are identified; can

be a list of named arguments to the showLabels function; TRUE is equivalent to

list(method=list(abs(residuals(model,type="pearson")), "x"), n=2, cex=1, col=carPalette(

which identifies the 2 points with the largest residuals and the 2 points with the

most extreme horizontal (X) values.

order order of polynomial regression performed for predictor to be plotted; default 1.

line TRUE to plot least-squares line.

smooth specifies the smoother to be used along with its arguments; if FALSE, no smoother

is shown; can be a list giving the smoother function and its named arguments;

TRUE, the default, is equivalent to list(smoother=loessLine). See ScatterplotSmoothers

for the smoothers supplied by the **car** package and their arguments.

col color for points; the default is the first entry in the current **car** palette (see

carPalette and par).

col.lines a list of at least two colors. The first color is used for the ls line and the second

color is used for the fitted lowess line. To use the same color for both, use, for

example, col.lines=c("red", "red")

xlab, ylab labels for the x and y axes, respectively. If not set appropriate labels are created

by the function.

pch plotting character for points; default is 1 (a circle, see par).

lwd line width; default is 2 (see par).

grid If TRUE, the default, a light-gray background grid is put on the graph.

Details

The function intended for direct use is crPlots, for which crp is an abbreviation.

The model cannot contain interactions, but can contain factors. Parallel boxplots of the partial residuals are drawn for the levels of a factor.

Value

NULL. These functions are used for their side effect of producing plots.

deltaMethod

Estimate and Standard Error of a Nonlinear Function of Estimated Regression Coefficients

Description

deltaMethod is a generic function that uses the delta method to get a first-order approximate standard error for a nonlinear function of a vector of random variables with known or estimated covariance matrix.

Usage

```
deltaMethod(object, ...)
## Default S3 method:
deltaMethod(object, g., vcov., func=g., constants, level=0.95,
   rhs, ..., envir=parent.frame())
## S3 method for class 'lm'
```

```
deltaMethod(object, g., vcov.=vcov(object, complete=FALSE),
          parameterNames=names(coef(object)), ..., envir=parent.frame())
## S3 method for class 'nls'
deltaMethod(object, g., vcov.=vcov(object, complete=FALSE), ..., envir=parent.frame())
## S3 method for class 'multinom'
deltaMethod(object, g., vcov. = vcov(object, complete=FALSE),
           parameterNames = if (is.matrix(coef(object)))
       colnames(coef(object)) else names(coef(object)), ..., envir=parent.frame())
## S3 method for class 'polr'
deltaMethod(object, g., vcov.=vcov(object, complete=FALSE), ..., envir=parent.frame())
## S3 method for class 'survreg'
deltaMethod(object, g., vcov. = vcov(object, complete=FALSE),
           parameterNames = names(coef(object)), ..., envir=parent.frame())
## S3 method for class 'coxph'
deltaMethod(object, g., vcov. = vcov(object, complete=FALSE),
           parameterNames = names(coef(object)), ..., envir=parent.frame())
## S3 method for class 'mer'
deltaMethod(object, g., vcov. = vcov(object, complete=FALSE),
           parameterNames = names(fixef(object)), ..., envir=parent.frame())
## S3 method for class 'merMod'
deltaMethod(object, g., vcov. = vcov(object, complete=FALSE),
          parameterNames = names(fixef(object)), ..., envir=parent.frame())
## S3 method for class 'lme'
deltaMethod(object, g., vcov. = vcov(object, complete=FALSE),
           parameterNames = names(fixef(object)), ..., envir=parent.frame())
## S3 method for class 'lmList'
deltaMethod(object, g., ..., envir=parent.frame())
```

Arguments

object

For the default method, object is either (1) a vector of p named elements, so names(object) returns a list of p character strings that are the names of the elements of object; or (2) a model object for which there are coef and vcov methods, and for which the named coefficient vector returned by coef is asymptotically normally distributed with asymptotic covariance matrix returned by vcov. For the other methods, object is a regression object for which coef(object) or fixef(object) returns a vector of parameter estimates.

g.

A quoted string that is the function of the parameter estimates to be evaluated; see the details below.

vcov.

The (estimated) covariance matrix of the coefficient estimates. For the default method, this argument is required. For all other methods, this argument must either provide the estimated covariance matrix or a function that when applied to object returns a covariance matrix. The default is to use the function vcov.

func

A quoted string used to annotate output. The default of func = g. is usually appropriate.

parameterNames A character vector of length p that gives the names of the parameters in the same order as they appear in the vector of estimates. This argument will be useful if

some of the names in the vector of estimates include special characters, like $I(x2^2)$, or x1:x2 that will confuse the numerical differentiation function. See

details below.

constants This argument is a named vector whose elements are constants that are used in

the f argument. It isn't generally necessary to specify this argument but it may

be convenient to do so.

level level for confidence interval, default 0.95.

rhs hypothesized value for the specified function of parameters; if absent no hypoth-

esis test is performed.

... Used to pass arguments to the generic method.

envir Environment in which g. is evaluated; not normally specified by the user.

Details

Suppose x is a random vector of length p that is at least approximately normally distributed with mean β and estimated covariance matrix C. Then any function $g(\beta)$ of β , is estimated by g(x), which is in large samples normally distributed with mean $g(\beta)$ and estimated variance h'Ch, where h is the first derivative of $g(\beta)$ with respect to β evaluated at x. This function returns both g(x) and its standard error, the square root of the estimated variance.

The default method requires that you provide x in the argument object, C in the argument vcov., and a text expression in argument g. that when evaluated gives the function g. The call names (object) must return the names of the elements of x that are used in the expression g..

Since the delta method is often applied to functions of regression parameter estimates, the argument object may be the name of a regression object from which the estimates and their estimated variance matrix can be extracted. In most regression models, estimates are returned by the coef(object) and the variance matrix from vcov(object). You can provide an alternative function for computing the sample variance matrix, for example to use a sandwich estimator.

For mixed models using lme4 or nlme, the coefficient estimates are returned by the fixef function, while for multinom, lmList and nlsList coefficient estimates are returned by coef as a matrix. Methods for these models are provided to get the correct estimates and variance matrix.

The argument g. must be a quoted character string that gives the function of interest. For example, if you set $m2 < -lm(Y \sim X1 + X2 + X1:X2)$, then deltaMethod(m2, "X1/X2") applies the delta method to the ratio of the coefficient estimates for X1 and X2. The argument g. can consist of constants and names associated with the elements of the vector of coefficient estimates.

In some cases the names may include characters such as the colon: used in interactions, or mathematical symbols like + or - signs that would confuse the function that computes numerical derivatives, and for this case you can replace the names of the estimates with the parameterNames argument. For example, the ratio of the X2 main effect to the interaction term could be computed using deltaMethod(m2, "b1/b3", parameterNames=c("b0", "b1", "b2", "b3")). The name "(Intercept)" used for the intercept in linear and generalized linear models is an exception, and it will be correctly interpreted by deltaMethod. Another option is to use back-ticks to quote nonstandard R names, as in deltaMethod(m2, "X1/`X1:X2`").

For multinom objects, the coef function returns a matrix of coefficients, with each row giving the estimates for comparisons of one category to the baseline. The deltaMethod function applies the delta method to each row of this matrix. Similarly, for lmList and nlsList objects, the delta method is computed for each element of the list of models fit.

For nonlinear regression objects produced by the nls function, the call coef(object) returns the estimated coefficient vectors with names corresponding to parameter names. For example, $m2 < -nls(y \sim theta/(1 + gamma * x), start = list(theta=2,gamma=3))$ will have parameters named c("theta", "gamma"). In many other familiar regression models, such as those produced by lm and glm, the names of the coefficient estimates are the corresponding regressor names, not parameter names.

For mixed-effects models fit with 1mer and glmer from the **lme4** package or 1me and nlme from the **nlme** package, only fixed-effect coefficients are considered.

For regression models for which methods are not provided, you can extract the named vector of coefficient estimates and and estimate of its covariance matrix and then apply the default deltaMethod function.

Note: Earlier versions of deltaMethod included an argument parameterPrefix that implemented the same functionality as the parameterNames argument, but which caused several problems that were not easily fixed without the change in syntax.

Value

An object of class "deltaMethod", inheriting from "data.frame", for which a print method is provided. The object contains columns named Estimate for the estimate, SE for its standard error, and columns for confidence limits and possibly a hypothesis test. The value of g. is given as a row label.

densityPlot 45

densityPlot

Nonparametric Density Estimates

Description

densityPlot contructs and graphs nonparametric density estimates, possibly conditioned on a factor, using the standard R density function or by default adaptiveKernel, which computes an adaptive kernel density estimate. depan provides the Epanechnikov kernel and dbiwt provides the biweight kernel.

Usage

```
densityPlot(x, ...)

## Default S3 method:
densityPlot(x, g, method=c("adaptive", "kernel"),
    bw=if (method == "adaptive") bw.nrd0 else "SJ", adjust=1,
    kernel, xlim, ylim,
    normalize=FALSE, xlab=deparse(substitute(x)), ylab="Density", main="",
    col=carPalette(), lty=seq_along(col), lwd=2, grid=TRUE,
    legend=TRUE, show.bw=FALSE, rug=TRUE, ...)

## S3 method for class 'formula'
densityPlot(formula, data=NULL, subset,
    na.action=NULL, xlab, ylab, main="", legend=TRUE, ...)

adaptiveKernel(x, kernel=dnorm, bw=bw.nrd0, adjust=1.0, n=500,
    from, to, cut=3, na.rm=TRUE)

depan(x)
dbiwt(x)
```

Arguments

X	a numeric variable, the density of which is estimated; for depan and dbiwt, the argument of the kernel function.
g	an optional factor to divide the data.
formula	an R model formula, of the form \sim variable to estimate the unconditional density of variable, or variable \sim factor to estimate the density of variable within each level of factor.
data	an optional data frame containing the data.
subset	an optional vector defining a subset of the data.
na.action	a function to handle missing values; defaults to the value of the R $na.action$ option, initially set to $na.omit$.
method	either "adaptive" (the default) for an adaptive-kernel estimate or "kernel" for a fixed-bandwidth kernel estimate.

46 densityPlot

bw the geometric mean bandwidth for the adaptive-kernel or bandwidth of the kernel density estimate(s). Must be a numerical value or a function to compute the bandwidth (default bw.nrd0) for the adaptive kernel estimate; for the kernel estimate, may either the quoted name of a rule to compute the bandwidth, or a numeric value. If plotting by groups, bw may be a vector of values, one for each group. See density and bw. SJ for details of the kernel estimator. adjust a multiplicative adjustment factor for the bandwidth; the default, 1, indicates no adjustment; if plotting by groups, adjust may be a vector of adjustment factors, one for each group. The default bandwidth-selection rule tends to give a value that's too large if the distribution is asymmetric or has multiple modes; try setting adjust < 1, particularly for the adaptive-kernel estimator. kernel for densityPlot this is the name of the kernel function for the kernel estimator (the default is "gaussian", see density); or a kernel function for the adaptive-kernel estimator (the default is dnorm, producing the Gaussian kernel). For adaptivekernel this is a kernel function, defaulting to dnorm, which is the Gaussian kernel (standard-normal density). xlim, ylim axis limits; if missing, determined from the range of x-values at which the densities are estimated and the estimated densities. normalize if TRUE (the default is FALSE), the estimated densities are rescaled to integrate approximately to 1; particularly useful if the density is estimated over a restricted domain, as when from or to are specified. xlab label for the horizontal-axis; defaults to the name of the variable x. ylab label for the vertical axis; defaults to "Density". main plot title; default is empty. col vector of colors for the density estimate(s); defaults to the color carPalette. lty vector of line types for the density estimate(s); defaults to the successive integers, starting at 1. lwd line width for the density estimate(s); defaults to 2. grid if TRUE (the default), grid lines are drawn on the plot. legend a list of up to two named elements: location, for the legend when densities are plotted for several groups, defaults to "upperright" (see legend); and title of the legend, which defaults to the name of the grouping factor. If TRUE, the default, the default values are used; if FALSE, the legend is suppressed. number of equally spaced points at which the adaptive-kernel estimator is evaln uated; the default is 500. from, to, cut the range over which the density estimate is computed; the default, if missing, is min(x) -cut*bw, max(x) + cut*bw. remove missing values from x in computing the adaptive-kernel estimate? The na.rm default is TRUE. if TRUE, show the bandwidth(s) in the horizontal-axis label or (for multiple show.bw groups) the legend; the default is FALSE. if TRUE (the default), draw a rug plot (one-dimentional scatterplot) at the bottom rug of the density estimate. arguments to be passed down to graphics functions.

densityPlot 47

Details

If you use a different kernel function than the default dnorm that has a standard deviation different from 1 along with an automatic rule like the default function bw.nrd0, you can attach an attribute to the kernel function named "scale" that gives its standard deviation. This is true for the two supplied kernels, depan and dbiwt

Value

densityPlot invisibly returns the "density" object computed (or list of "density" objects) and draws a graph. adaptiveKernel returns an object of class "density" (see density).

48 dfbetaPlots

dfbetaPlots

dfbeta and dfbetas Index Plots

Description

These functions display index plots of dfbeta (effect on coefficients of deleting each observation in turn) and dfbetas (effect on coefficients of deleting each observation in turn, standardized by a deleted estimate of the coefficient standard error). In the plot of dfbeta, horizontal lines are drawn at 0 and +/- one standard error; in the plot of dfbetas, horizontal lines are drawn and 0 and +/- 1.

Usage

```
dfbetaPlots(model, ...)

## S3 method for class 'lm'
dfbetaPlots(model, terms= ~ ., intercept=FALSE, layout=NULL, ask,
    main, xlab, ylab, labels=rownames(dfbeta),
        id.method="y",
        id.n=if(id.method[1]=="identify") Inf else 0, id.cex=1,
        id.col=carPalette()[1], id.location="lr", col=carPalette()[1], grid=TRUE, ...)

## S3 method for class 'lm'
dfbetasPlots(model, terms=~., intercept=FALSE, layout=NULL, ask,
        main, xlab, ylab,
        labels=rownames(dfbetas), id.method="y",
        id.n=if(id.method[1]=="identify") Inf else 0, id.cex=1,
        id.col=carPalette()[1], id.location="lr", col=carPalette()[1], grid=TRUE, ...)
```

Arguments

model model object produced by 1m or g1m.

terms A one-sided formula that specifies a subset of the terms in the model. One

dfbeta or dfbetas plot is drawn for each regressor. The default \sim . is to plot against all terms in the model with the exception of an intercept. For example, the specification terms = \sim .-X3 would plot against all terms except for X3. If this argument is a quoted name of one of the terms, the index plot is drawn for

that term only.

intercept Include the intercept in the plots; default is FALSE.

dfbetaPlots 49

layout	If set to a value like c(1,1) or c(4,3), the layout of the graph will have this many rows and columns. If not set, the program will select an appropriate layout. If the number of graphs exceed nine, you must select the layout yourself, or you will get a maximum of nine per page. If layout=NA, the function does not set the layout and the user can use the par function to control the layout, for example to have plots from two models in the same graphics window.
main	The title of the graph; if missing, one will be supplied.
xlab	Horizontal axis label; defaults to "Index".
ylab	Vertical axis label; defaults to coefficient name.
ask	If TRUE, ask the user before drawing the next plot; if FALSE, the default, don't ask.
	optional additional arguments to be passed to plot, points, and showLabels.
id.method, labe	els, id.n, id.cex, id.col, id.location Arguments for the labelling of points. The default is id.n=0 for labeling no points. See showLabels for details of these arguments.
col	color for points; defaults to the first entry in the color carPalette.
grid	If TRUE, the default, a light-gray background grid is put on the graph

Value

NULL. These functions are used for their side effect: producing plots.

50 durbinWatsonTest

durbinWatsonTest Durbin-Watson Test for Autocorrelated Errors

Description

Computes residual autocorrelations and generalized Durbin-Watson statistics and their bootstrapped p-values. dwt is an abbreviation for durbinWatsonTest.

Usage

```
durbinWatsonTest(model, ...)

dwt(...)

## S3 method for class 'lm'
durbinWatsonTest(model, max.lag=1, simulate=TRUE, reps=1000,
    method=c("resample","normal"),
    alternative=c("two.sided", "positive", "negative"), ...)

## Default S3 method:
durbinWatsonTest(model, max.lag=1, ...)

## S3 method for class 'durbinWatsonTest'
print(x, ...)
```

Arguments

model	a linear-model object, or a vector of residuals from a linear model.
max.lag	maximum lag to which to compute residual autocorrelations and Durbin-Watson statistics.
simulate	if TRUE p-values will be estimated by bootstrapping.
reps	number of bootstrap replications.
method	bootstrap method: "resample" to resample from the observed residuals; "normal" to sample normally distributed errors with 0 mean and standard deviation equal to the standard error of the regression.
alternative	sign of autocorrelation in alternative hypothesis; specify only if max.lag = 1; if max.lag > 1, then alternative is taken to be "two.sided".
	arguments to be passed down.
x	durbinWatsonTest object.

Value

Returns an object of type "durbinWatsonTest".

Note

p-values are available only from the 1m method.

Ellipses

Ellipses, Data Ellipses, and Confidence Ellipses

Description

These functions draw ellipses, including data ellipses, and confidence ellipses for linear, generalized linear, and possibly other models.

Usage

```
ellipse(center, shape, radius, log="", center.pch=19, center.cex=1.5,
  segments=51, draw=TRUE, add=draw, xlab="", ylab="";
  col=carPalette()[2], lwd=2, fill=FALSE, fill.alpha=0.3, grid=TRUE, ...)
dataEllipse(x, y, groups, group.labels=group.levels, ellipse.label,
 weights, log="", levels=c(0.5, 0.95), center.pch=19,
 center.cex=1.5, draw=TRUE, plot.points=draw, add=!plot.points, segments=51,
  robust=FALSE, xlab=deparse(substitute(x)), ylab=deparse(substitute(y)),
 col=if (missing(groups)) carPalette()[1:2] else carPalette()[1:length(group.levels)],
  pch=if (missing(groups)) 1 else seq(group.levels),
 lwd=2, fill=FALSE, fill.alpha=0.3, grid=TRUE, id=FALSE, ...)
confidenceEllipse(model, ...)
## S3 method for class 'lm'
confidenceEllipse(model, which.coef, vcov.=vcov,
 L, levels=0.95, Scheffe=FALSE, dfn,
 center.pch=19, center.cex=1.5, segments=51, xlab, ylab,
 col=carPalette()[2], lwd=2, fill=FALSE, fill.alpha=0.3, draw=TRUE, add=!draw, ...)
## S3 method for class 'glm'
confidenceEllipse(model, chisq, ...)
```

```
## Default S3 method:
confidenceEllipse(model, which.coef, vcov.=vcov,
   L, levels=0.95, Scheffe=FALSE, dfn,
   center.pch=19, center.cex=1.5, segments=51, xlab, ylab,
   col=carPalette()[2], lwd=2, fill=FALSE, fill.alpha=0.3, draw=TRUE, add=!draw, ...)
```

Arguments

center 2-element vector with coordinates of center of ellipse.

shape 2×2 shape (or covariance) matrix. radius radius of circle generating the ellipse.

log when an ellipse is to be added to an existing plot, indicates whether computa-

tions were on logged values and to be plotted on logged axes; "x" if the x-axis is logged, "y" if the y-axis is logged, and "xy" or "yx" if both axes are logged.

The default is "", indicating that neither axis is logged.

center.pch character for plotting ellipse center; if FALSE or NULL the center point isn't plot-

ted.

center.cex relative size of character for plotting ellipse center.
segments number of line-segments used to draw ellipse.

draw if TRUE produce graphical output; if FALSE, only invisibly return coordinates of

ellipse(s).

add if TRUE add ellipse(s) to current plot.

xlab label for horizontal axis. ylab label for vertical axis.

x a numeric vector, or (if y is missing) a 2-column numeric matrix.

y a numeric vector, of the same length as x.

groups optional: a factor to divide the data into groups; a separate ellipse will be plotted

for each group (level of the factor).

group.labels labels to be plotted for the groups; by default, the levels of the groups factor.

ellipse.label a label for the ellipse(s) or a vector of labels; if several ellipses are drawn and

just one label is given, then that label will be repeated. The default is not to label

the ellipses.

weights a numeric vector of weights, of the same length as x and y to be used by cov.wt

or cov. trob in computing a weighted covariance matrix; if absent, weights of

1 are used.

plot.points if FALSE data ellipses are drawn, but points are not plotted.

levels draw elliptical contours at these (normal) probability or confidence levels.

robust if TRUE use the cov. trob function in the MASS package to calculate the center

and covariance matrix for the data ellipse.

model a model object produced by 1m or glm.

which.coef 2-element vector giving indices of coefficients to plot; if missing, the first two

coefficients (disregarding the regression constant) will be selected.

vcov. a coefficient-covariance matrix or a function (such as hccm) to compute the coefficient-covariance matrix from model; the default is the vcov function.

As an alternative to selecting coefficients to plot, a transformation matrix can be specified to compute two linear combinations of the coefficients; if the L matrix is given, it takes precedence over the which coef argument. L should have two rows and as many columns as there are coefficients. It can be given directly as a numeric matrix, or specified by a pair of character-valued expressions, in the same manner as for the link{linearHypothesis} function, but with no

right-hand side.

Scheffe if TRUE scale the ellipse so that its projections onto the axes give Scheffe confi-

dence intervals for the coefficients.

dfn "numerator" degrees of freedom (or just degrees of freedom for a GLM) for

drawing the confidence ellipse. Defaults to the number of coefficients in the model (disregarding the constant) if Scheffe is TRUE, or to 2 otherwise; selecting dfn = 1 will draw the "confidence-interval generating" ellipse, with projections on the axes corresponding to individual confidence intervals with the stated

level of coverage.

chisq if TRUE, the confidence ellipse for the coefficients in a generalized linear model

are based on the chisquare statistic, if FALSE on the \$F\$-statistic. This corre-

sponds to using the default and linear-model methods respectively.

col color for lines and ellipse center; the default is the *second* entry in the current

car palette (see carPalette and par). For dataEllipse, two colors can be given, in which case the first is for plotted points and the second for lines and the ellipse center; if ellipses are plotted for groups, then this is a vector of colors

for the groups.

pch for dataEllipse this is the plotting character (default, symbol 1, a hollow cir-

cle) to use for the points; if ellipses are plotted by groups, then this a vector of plotting characters, with consecutive symbols starting with 1 as the default.

lwd line width; default is 2 (see par).

fill fill the ellipse with translucent color col (default, FALSE)?

fill.alpha transparency of fill (default = 0.3).

... other plotting parameters to be passed to plot and line.

id controls point identification; if FALSE (the default), no points are identified; can

be a list of named arguments to the showLabels function; TRUE is equivalent to list(method="mahal", n=2, cex=1, col=carPalette()[1], location="lr") (with the default col actually dependent on the number of groups), which identifies the 2 points with the largest Mahalanobis distances from the center of the

data.

grid If TRUE, the default, a light-gray background grid is put on the graph

Details

L

The ellipse is computed by suitably transforming a unit circle.

dataEllipse superimposes the normal-probability contours over a scatterplot of the data.

Value

These functions are mainly used for their side effect of producing plots. For greater flexibility (e.g., adding plot annotations), however, ellipse returns invisibly the (x, y) coordinates of the calculated ellipse. dataEllipse and confidenceEllipse return invisibly the coordinates of one or more ellipses, in the latter instance a list named by levels.

```

Export 55

Export	Export a data frame to disk in one of many formats

Description

Uses the export function in the **rio** package to export a file to disk. This function adds an argument for converting row.names to a column in the resulting file.

Usage

```
Export(x, file, format, ..., keep.row.names)
```

Arguments

A data frame or matrix to be written to a file.

file A character string naming a file. If the file name has an extension, such as .xlsx,

the extention is used to infer the type of file to be exported. See export for the

file types supported.

format see export.

... Additional arguments; see export.

keep.row.names If set to TRUE, then the data frame's row.names are appended to the left of the

data frame with the name "id". If set to quoted character string, the row.names are added using the character string as its name. If set to FALSE row.names are

lost.

Details

This is a convenience function in the **car** package for exporting (writing) a data frame to a file in a wide variety of formats including csv, Microsoft Excel. It optionally allows converting the row.names for the data frame to a column before writing. It then calls **export** in the rio package. That function in turn uses many other packages and functions for writing the function to a file.

Value

The name of the output file as a character string (invisibly).

hccm

Heteroscedasticity-Corrected Covariance Matrices

Description

Calculates heteroscedasticity-corrected covariance matrices linear models fit by least squares or weighted least squares. These are also called "White-corrected" or "White-Huber" covariance matrices.

Usage

```
hccm(model, ...)
## S3 method for class 'lm'
hccm(model, type=c("hc3", "hc0", "hc1", "hc2", "hc4"),
singular.ok=TRUE, ...)
## Default S3 method:
hccm(model, ...)
```

Arguments

model	a unweighted or weighted linear model, produced by 1m.
type	one of "hc0", "hc1", "hc2", "hc3", or "hc4"; the first of these gives the classic White correction. The "hc1", "hc2", and "hc3" corrections are described in Long and Ervin (2000); "hc4" is described in Cribari-Neto (2004).
singular.ok	if FALSE (the default is TRUE), a model with aliased coefficients produces an error; otherwise, the aliased coefficients are ignored in the coefficient covariance matrix that's returned.
	arguments to pass to hccm. lm.

hccm 57

Details

The original White-corrected coefficient covariance matrix ("hc0") for an unweighted model is

$$V(b) = (X'X)^{-1}X'diag(e_i^2)X(X'X)^{-1}$$

where e_i^2 are the squared residuals, and X is the model matrix. The other methods represent adjustments to this formula. If there are weights, these are incorporated in the corrected covariance matrix.

The function hccm. default simply catches non-lm objects.

See Freedman (2006) and Fox and Weisberg(2019, Sec. 5.1.2) for discussion of the use of these methods in generalized linear models or models with nonconstant variance.

Value

The heteroscedasticity-corrected covariance matrix for the model.

Author(s)

John Fox <ifox@mcmaster.ca>

58 hist.boot

hist.boot

Methods Functions to Support boot Objects

Description

The Boot function in the **car** package uses the **boot** function from the **boot** package to do a straightforward case or residual bootstrap for many regression objects. These are method functions for standard generics to summarize the results of the bootstrap. Other tools for this purpose are available in the boot package.

Usage

```
## S3 method for class 'boot'
hist(x, parm, layout = NULL, ask, main = "", freq = FALSE,
    estPoint = TRUE, point.col = carPalette()[1], point.lty = 2, point.lwd = 2,
    estDensity = !freq, den.col = carPalette()[2], den.lty = 1, den.lwd = 2,
    estNormal = !freq, nor.col = carPalette()[3], nor.lty = 2, nor.lwd = 2,
    ci = c("bca", "none", "perc", "norm"), level = 0.95,
    legend = c("top", "none", "separate"), box = TRUE, ...)
## S3 method for class 'boot'
summary(object, parm, high.moments = FALSE, extremes = FALSE, ...)
## S3 method for class 'boot'
confint(object, parm, level = 0.95, type = c("bca", "norm",
    "basic", "perc"), ...)
## S3 method for class 'boot'
Confint(object, parm, level = 0.95, type = c("bca", "norm",
    "basic", "perc"), ...)
## S3 method for class 'boot'
vcov(object, use="complete.obs", ...)
```

Arguments

x, object An object created by a call to boot in the boot package, or to Boot in the car package of class "boot".

parm A vector of numbers or coefficient names giving the coefficients for which a histogram or confidence interval is desired. If numbers are used, 1 corresponds

to the intercept, if any. The default is all coefficients.

hist.boot 59

layout If set to a value like c(1,1) or c(4,3), the layout of the graph will have this

many rows and columns. If not set, the program will select an appropriate layout. If the number of graphs exceed nine, you must select the layout yourself, or you will get a maximum of nine per page. If layout=NA, the function does not set the layout and the user can use the par function to control the layout, for example

to have plots from two models in the same graphics window.

ask If TRUE, ask the user before drawing the next plot; if FALSE, don't ask.

main Main title for the graphs. The default is main="" for no title.

freq The default for the generic hist function is freq=TRUE to give a frequency his-

togram. The default for hist.boot is freq=FALSE to give a density histogram. A density estimate and/or a fitted normal density can be added to the graph if

freq=FALSE but not if freq=TRUE.

estPoint, point.col, point.lty, point.lwd

If estPoint=TRUE, the default, a vertical line is drawn on the histgram at the value of the point estimate computed from the complete data. The remaining three optional arguments set the color, line type and line width of the line that is

drawn.

estDensity, den.col, den.lty, den.lwd

If estDensity=TRUE andfreq=FALSE, the default, a kernel density estimate is drawn on the plot with a call to the density function with no additional arguments. The remaining three optional arguments set the color, line type and line

width of the lines that are drawn.

estNormal, nor.col, nor.lty, nor.lwd

If estNormal=TRUE andfreq=FALSE, the default, a normal density with mean and sd computed from the data is drawn on the plot. The remaining three optional arguments set the color, line type and line width of the lines that are drawn.

ci A confidence interval based on the bootstrap will be added to the histogram

using the BCa method if ci="bca" the percentile method if ci="perc", or the normal method if ci="norm". No interval is drawn if ci="none". The default is "bca". The interval is indicated by a thick horizontal line at y=0. For some bootstraps the BCa method is unavailable, in which case a warning is issued and ci="perc" is substituted. If you wish to see all the options at once, see boot.ci. The normal method is computed as the (estimate from the original data) minus the bootstrap bias plus or minus the standard deviation of the bootstrap replicates

times the appropriate quantile of the standard normal distribution.

A legend can be added to the (array of) histograms. The value "top" puts at the top-left of the plots. The value "separate" puts the legend in its own graph

following all the histograms. The value "none" suppresses the legend.

box Add a box around each histogram.

legend

... Additional arguments passed to hist; for other methods this is included for

compatibility with the generic method. For example, the argument border=par()\$bg in hist will draw the histogram transparently, leaving only the density estimates. With the vcov function, the additional arguments are passed to cov. See

the Value section, below.

high.moments Should the skewness and kurtosis be included in the summary? Default is

FALSE.

60 hist.boot

extremes	Should the minimum, maximum and range be included in the summary? Default is FALSE.
level	Confidence level, a number between 0 and 1. In confint, level can be a vector; for example level=c(.50,.90,.95) will return the following estimated quantiles: c(.025,.05,.25,.75,.95,.975).
type	Selects the confidence interval type. The types implemented are the "percentile' method, which uses the function quantile to return the appropriate quantiles for the confidence limit specified, the default bca which uses the bias-corrected and accelerated method presented by Efron and Tibshirani (1993, Chapter 14). For the other types, see the documentation for boot.
use	The default use="complete.obs" for vcov computes a bootstrap covariance matrix by deleting bootstraps that returned NAs. Setting use to anything else

Value

hist is used for the side-effect of drawing an array of historgams of each column of the first argument. summary returns a matrix of summary statistics for each of the columns in the bootstrap object. The confint method returns confidence intervals. Confint appends the estimates based on the original fitted model to the left of the confidence intervals.

The function vcov returns the sample covariance of the bootstrap sample estimates, by default skipping any bootstrap samples that returned NA.

Import 61

Import Import data from many file formats			
	Import	Import data from many file formats	
	•	1	

Description

Uses the import function from the **rio** package to read a data.frame from a variety of file types. The Import function includes 2 additional arguments adding row names and for converting character and logical variables to factors for some file types.

Usage

Arguments

file	A character string naming a file, URL, or .zip or .tar archive. See the details below. If the file name has an extension like .xlsx or .csv then the type of file is inferred from the extension.
format	If an extension is not present in the file name or it is wrong, the file format can be set with this argument; see import.
	Additional arguments passed to import.
row.names	If TRUE, the default, the left-most character variable that has all unique elements is removed from the data frame and set to be row.names. To match import, set row.names=FALSE.

stringsAsFactors

If TRUE, then character variables that do not have all unique elements are converted to factors. The default is FALSE. Prior to May 2020 the default was determined by getOption("stringsAsFactors"), which then defaulted to TRUE. This option is FALSE in R 4.0.0 and has been deprecated.

Details

This function calls the import function to read a data frame from a file. Many file types are supported. For files of type "txt", "csv", "xlsx", "xls" or "ods" the arguments row.names and stringsAsFactors can be used to add row names and convert character variables to factors, respectively. Many more details are given on the man page for import.

Value

```
A data frame. See import for more details
```

infIndexPlot

Influence Index Plot

Description

Provides index plots of influence and related diagnostics for a regression model.

Usage

```
infIndexPlot(model, ...)

## S3 method for class 'lm'
infIndexPlot(model, vars=c("Cook", "Studentized", "Bonf", "hat"),
    id=TRUE, grid=TRUE, main="Diagnostic Plots", ...)

## S3 method for class 'influence.merMod'
infIndexPlot(model,
    vars = c("dfbeta", "dfbetas", "var.cov.comps",
        "cookd"), id = TRUE, grid = TRUE, main = "Diagnostic Plots", ...)

## S3 method for class 'influence.lme'
infIndexPlot(model,
    vars = c("dfbeta", "dfbetas", "var.cov.comps",
    "cookd"), id = TRUE, grid = TRUE, main = "Diagnostic Plots", ...)
```

infIndexPlot 63

Arguments

model	A regression object of class lm, glm, or lmerMod, or an influence object for a lmer, glmer, or lme object (see influence.mixed.models). The "lmerMod" method calls the "lm" method and can take the same arguments.
vars	All the quantities listed in this argument are plotted. Use "Cook" for Cook's distances, "Studentized" for Studentized residuals, "Bonf" for Bonferroni p-values for an outlier test, and and "hat" for hat-values (or leverages) for a linear or generalized linear model, or "dfbeta", "dfbetas", "var.cov.comps", and "cookd" for an influence object derived from a mixed model. Capitalization is optional. All but "dfbeta" and "dfbetas" may be abbreviated by the first one or more letters.
main	main title for graph
id	a list of named values controlling point labelling. The default, TRUE, is equivalent to id=list(method="y",n=2,cex=1,col=carPalette()[1],location="lr"); FALSE suppresses point labelling. See showLabels for details.
grid	If TRUE, the default, a light-gray background grid is put on the graph.
	Arguments passed to plot

Value

Used for its side effect of producing a graph. Produces index plots of diagnostic quantities.

influence.mixed.models

Influence Diagnostics for Mixed-Effects Models

Description

These functions compute deletion influence diagnostics for linear mixed-effects models fit by lme in the **nlme** package. The main function is a method for the influence generic function. Other functions are provided for computing dfbeta, dfbetas, cooks.distance, and influence on variance-covariance components based on the object computed by influence.lme.

Usage

```
## S3 method for class 'lme'
influence(model, groups, data, ncores=1, ...)
## S3 method for class 'influence.lme'
cooks.distance(model, ...)
## S3 method for class 'influence.lme'
dfbeta(model, which = c("fixed", "var.cov"), ...)
## S3 method for class 'influence.lme'
dfbetas(model, ...)
```

Arguments

model in the case

in the case influence, a model of class "lme"; in the case of cooks.distance, dfbeta, or dfbetas, an object returned by influence.lme.

dibeta, of dibetas, an object letained by 1111 facilities. 111

groups

a character vector containing the name of a grouping factor or names of grouping factors; if more than one name is supplied, then groups are defined by all combinations of levels of the grouping factors that appear in the data. If omitted, then each individual row of the data matrix is treated as a "group" to be deleted in turn.

influence.mixed.models 65

data	an optional data frame with the data to which model was fit; influence.lme can access the data unless keep.data=FALSE was specified in the call to lme, so it's usually unnecessary to supply the data argument.
ncores	number of cores for parallel computation of diagnostics; if 1 (the default), the computation isn't parallelized; if Inf, all of the available <i>physical</i> cores (not necessarily <i>logical</i> cores — see detectCores) on the computer will be used.
which	if "fixed.effects" (the default), return influence on the fixed effects; if "var.cov", return influence on the variance-covariance components.
	ignored.

Details

influence.lme starts with the estimated variance-covariance components from model and then refits the model omitting each group in turn.

The other functions are methods for the dfbeta, dfbetas, and cooks.distance generics, to be applied to the "influence.lme" object produced by the influence function; the dfbeta methods can also return influence on the variance-covariance components.

Value

influence.lme returns an object of class "influence.lme", which contains the following elements:

"fixed.effects" the estimated fixed effects for the model.

"fixed.effects[-groups]" a matrix with columns corresponding to the fixed-effects coefficients and rows corresponding to groups, giving the estimated fixed effects with each group deleted in turn; *groups* is formed from the name(s) of the grouping factor(s).

"var.cov.comps" the estimated variance-covariance parameters for the model.

"var.cov.comps[-groups]" a matrix with the estimated covariance parameters (in columns) with each group deleted in turn.

"vcov" The estimated covariance matrix of the fixed-effects coefficients.

"vcov[-groups]" a list each of whose elements is the estimated covariance matrix of the fixed-effects coefficients with one group deleted.

"groups" a character vector giving the names of the grouping factors.

"deleted" the possibly composite grouping factor, each of whose elements is deleted in turn.

For plotting "influence.lme" objects, see inflndexPlot.

    infIndexPlot(influence(fm1))
    }</pre>
```

influencePlot

Regression Influence Plot

Description

This function creates a "bubble" plot of Studentized residuals versus hat values, with the areas of the circles representing the observations proportional to the value Cook's distance. Vertical reference lines are drawn at twice and three times the average hat value, horizontal reference lines at -2, 0, and 2 on the Studentized-residual scale.

Usage

```
influencePlot(model, ...)
## S3 method for class 'lm'
influencePlot(model, scale=10,
    xlab="Hat-Values", ylab="Studentized Residuals", id=TRUE, ...)
## S3 method for class 'lmerMod'
influencePlot(model, ...)
```

Arguments

model a linear, generalized-linear, or linear mixed model; the "lmerMod" method calls

the "lm" method and can take the same arguments.

scale a factor to adjust the size of the circles.

xlab, ylab axis labels.

id settings for labelling points; see link{showLabels} for details. To omit point

labelling, set id=FALSE; the default, id=TRUE is equivalent to id=list(method="noteworthy", n=2, cex

The default method="noteworthy" is used only in this function and indicates setting labels for points with large Studentized residuals, hat-values or Cook's distances. Set id=list(method="identify") for interactive point identifica-

tion.

... arguments to pass to the plot and points functions.

invResPlot 67

Value

If points are identified, returns a data frame with the hat values, Studentized residuals and Cook's distance of the identified points. If no points are identified, nothing is returned. This function is primarily used for its side-effect of drawing a plot.

## End(Not run)
```

invResPlot

Inverse Response Plots to Transform the Response

Description

For a 1m model, draws an inverse response plot with the response Y on the vertical axis and the fitted values \hat{Y} on the horizontal axis. Uses n1s to estimate λ in the function $\hat{Y} = b_0 + b_1 Y^{\lambda}$. Adds the fitted curve to the plot. invResPlot is an alias for inverseResponsePlot.

Usage

```
inverseResponsePlot(model, lambda=c(-1,0,1), robust=FALSE, xlab=NULL, ...)
## S3 method for class 'lm'
inverseResponsePlot(model, lambda=c(-1, 0, 1),
    robust=FALSE, xlab=NULL, id=FALSE, ...)
invResPlot(model, ...)
```

68 invResPlot

Arguments

model	A "lm" regression object.
lambda	A vector of values for lambda. A plot will be produced with curves corresponding to these lambdas and to the nonlinear least squares estimate of lambda.
robust	If TRUE, then estimation uses Huber M-estimates with the median absolute deviation to estimate scale and k= 1.345. The default is FALSE.
xlab	The horizontal axis label. If NULL, it is constructed by the function.
id	controls point identification; if FALSE (the default), no points are identified; can be a list of named arguments to the showLabels function; TRUE is equivalent to list(method="x",n=2,cex=1,col=carPalette()[1],location="lr"), which identifies the 2 points with the most extreme horizontal (X) values.
• • •	Other arguments passed to invTranPlot and then to plot.

Value

As a side effect, a plot is produced with the response on the horizontal axis and fitted values on the vertical axis. Several lines are added to be plot as the ols estimates of the regression of \hat{Y} on Y^{λ} , interpreting $\lambda = 0$ to be natural logarithms.

Numeric output is a list with elements

lambda Estimate of transformation parameter for the response

RSS The residual sum of squares at the minimum if robust=FALSE. If robust =

TRUE, the value of Huber objective function is returned.

invTranPlot 69

invTranPlot	Choose a Predictor Transformation Visually or Numerically

Description

invTranPlot draws a two-dimensional scatterplot of Y versus X, along with the OLS fit from the regression of Y on $(X^{\lambda}-1)/\lambda$. invTranEstimate finds the nonlinear least squares estimate of λ and its standard error.

Usage

Arguments

X	The predictor variable, or a formula with a single response and a single predictor
у	The response variable
data	An optional data frame to get the data for the formula
subset	Optional, as in 1m, select a subset of the cases
na.action	Optional, as in 1m, the action for missing data
lambda	The powers used in the plot. The optimal power than minimizes the residual sum of squares is always added unless optimal is FALSE.
robust	If TRUE, then the estimated transformation is computed using Huber M-estimation with the MAD used to estimate scale and $k=1.345$. The default is FALSE.
family	The transformation family to use, "bcPower", "yjPower", or a user-defined family.
confidence	returns a profile likelihood confidence interval for the optimal transformation with this confidence level. If FALSE, or if robust=TRUE, no interval is returned.
optimal	Include the optimal value of lambda?

70 invTranPlot

lty.lines	line types corresponding to the powers
lwd.lines	the width of the plotted lines, defaults to 2 times the standard
col	color(s) of the points in the plot. If you wish to distinguish points according to the levels of a factor, we recommend using symbols, specified with the pch argument, rather than colors.
col.lines	color of the fitted lines corresponding to the powers. The default is to use the colors returned by carPalette
key	The default is "auto", in which case a legend is added to the plot, either above the top marign or in the bottom right or top right corner. Set to NULL to suppress the legend.
xlab	Label for the horizontal axis.
ylab	Label for the vertical axis.
id	controls point identification; if FALSE (the default), no points are identified; can be a list of named arguments to the showLabels function; TRUE is equivalent to list(method=list(method="x",n=2,cex=1,col=carPalette()[1],location="lr"), which identifies the 2 points with the most extreme horizontal values — i.e., the response variable in the model.
• • •	Additional arguments passed to the plot method, such as pch.
grid	If TRUE, the default, a light-gray background grid is put on the graph

Value

invTranPlot plots a graph and returns a data frame with λ in the first column, and the residual sum of squares from the regression for that λ in the second column.

invTranEstimate returns a list with elements lambda for the estimate, se for its standard error, and RSS, the minimum value of the residual sum of squares.

leveneTest 71

|--|

Description

Computes Levene's test for homogeneity of variance across groups.

Usage

```
leveneTest(y, ...)
## S3 method for class 'formula'
leveneTest(y, data, ...)
## S3 method for class 'lm'
leveneTest(y, ...)
## Default S3 method:
leveneTest(y, group, center=median, ...)
```

Arguments

У	response variable for the default method, or a 1m or formula object. If y is a linear-model object or a formula, the variables on the right-hand-side of the model must all be factors and must be completely crossed.
group	factor defining groups.
center	The name of a function to compute the center of each group; mean gives the original Levene's test; the default, median, provides a more robust test.
data	a data frame for evaluating the formula.
	arguments to be passed down, e.g., data for the formula and lm methods; can also be used to pass arguments to the function given by center (e.g., center=mean and trim=0.1 specify the 10% trimmed mean).

Value

returns an object meant to be printed showing the results of the test.

Note

adapted from a response posted by Brian Ripley to the r-help email list.

leveragePlots

Regression Leverage Plots

Description

These functions display a generalization, due to Sall (1990) and Cook and Weisberg (1991), of added-variable plots to multiple-df terms in a linear model. When a term has just 1 df, the leverage plot is a rescaled version of the usual added-variable (partial-regression) plot.

Usage

Arguments

model

model object produced by 1m

terms

A one-sided formula that specifies a subset of the numeric regressors, factors and interactions. One added-variable plot is drawn for each term, either a main effect or an interactions. The default \sim . is to plot against all terms in the model. For example, the specification terms = \sim . -X3 would plot against all predictors except for X3. If this argument is a quoted name of one of the predictors, the added-variable plot is drawn for that predictor only. The plots for main effects with interactions present violate the marginality principle and may not be easily interpreted.

layout

If set to a value like c(1,1) or c(4,3), the layout of the graph will have this many rows and columns. If not set, the program will select an appropriate layout. If the number of graphs exceed nine, you must select the layout yourself, or you

leveragePlots 73

will get a maximum of nine per page. If layout=NA, the function does not set the layout and the user can use the par function to control the layout, for example

to have plots from two models in the same graphics window.

ask if TRUE, a menu is provided in the R Console for the user to select the term(s) to

plot.

xlab, ylab axis labels; if missing, labels will be supplied.

main title for plot; if missing, a title will be supplied.

... arguments passed down to method functions.

term.name Quoted name of term in the model to be plotted; this argument is omitted for

leveragePlots.

id controls point identification; if FALSE, no points are identified; can be a list of

named arguments to the showLabels function; TRUE, the default, is equivalent to

list(method=list(abs(residuals(model,type="pearson")),"x"),n=2,cex=1,col=carPalette(

which identifies the 2 points with the largest residuals and the 2 points with the

greatest partial leverage.

col color(s) of points
col.lines color of the fitted line

lwd line width; default is 2 (see par).

grid If TRUE, the default, a light-gray background grid is put on the graph

Details

The function intended for direct use is leveragePlots.

The model can contain factors and interactions. A leverage plot can be drawn for each term in the model, including the constant.

leveragePlot.glm is a dummy function, which generates an error message.

Value

NULL. These functions are used for their side effect: producing plots.

linearHypothesis

Test Linear Hypothesis

Description

Generic function for testing a linear hypothesis, and methods for linear models, generalized linear models, multivariate linear models, linear and generalized linear mixed-effects models, generalized linear models fit with svyglm in the **survey** package, robust linear models fit with rlm in the **MASS** package, and other models that have methods for coef and vcov. For mixed-effects models, the tests are Wald chi-square tests for the fixed effects.

Usage

```
linearHypothesis(model, ...)
lht(model, ...)
## Default S3 method:
linearHypothesis(model, hypothesis.matrix, rhs=NULL,
test=c("Chisq", "F"), vcov.=NULL, singular.ok=FALSE, verbose=FALSE,
   coef. = coef(model), suppress.vcov.msg=FALSE, ...)
## S3 method for class 'lm'
linearHypothesis(model, hypothesis.matrix, rhs=NULL,
    test=c("F", "Chisq"), vcov.=NULL,
white.adjust=c(FALSE, TRUE, "hc3", "hc0", "hc1", "hc2", "hc4"),
singular.ok=FALSE, ...)
## S3 method for class 'glm'

```

Arguments

mode1

rhs

fitted model object. The default method of linear Hypothesis works for models for which the estimated parameters can be retrieved by coef and the corresponding estimated covariance matrix by vcov. See the Details for more information.

hypothesis.matrix

matrix (or vector) giving linear combinations of coefficients by rows, or a character vector giving the hypothesis in symbolic form (see *Details*).

right-hand-side vector for hypothesis, with as many entries as rows in the hypothesis matrix; can be omitted, in which case it defaults to a vector of zeroes. For a multivariate linear model, rhs is a matrix, defaulting to 0. This argument

isn't available for F-tests for linear mixed models.

singular.ok if FALSE (the default), a model with aliased coefficients produces an error; if

TRUE, the aliased coefficients are ignored, and the hypothesis matrix should not have columns for them. For a multivariate linear model: will return the hypothesis and error SSP matrices even if the latter is singular; useful for computing univariate repeated-measures ANOVAs where there are fewer subjects than df

for within-subject effects.

an optional data frame giving a factor or factors defining the intra-subject model

for multivariate repeated-measures data. See Details for an explanation of the intra-subject design and for further explanation of the other arguments relating

to intra-subject factors.

names of contrast-generating functions to be applied by default to factors and

ordered factors, respectively, in the within-subject "data"; the contrasts must produce an intra-subject model matrix in which different terms are orthogonal.

a one-sided model formula using the "data" in idata and specifying the intraidesign

subject design.

iterms the quoted name of a term, or a vector of quoted names of terms, in the intra-

subject design to be tested.

check.imatrix check that columns of the intra-subject model matrix for different terms are mu-

tually orthogonal (default, TRUE). Set to FALSE only if you have already checked

that the intra-subject model matrix is block-orthogonal.

transformation matrix to be applied to the repeated measures in multivariate repeated-measures data; if NULL and no intra-subject model is specified, no

response-transformation is applied; if an intra-subject model is specified via the idata, idesign, and (optionally) icontrasts arguments, then P is generated

automatically from the iterms argument.

SSPE in linear Hypothesis method for mlm objects: optional error sum-of-squares-

> and-products matrix; if missing, it is computed from the model. In print method for linear Hypothesis. mlm objects: if TRUE, print the sum-of-squares

and cross-products matrix for error.

character string, "F" or "Chisq", specifying whether to compute the finitetest

sample F statistic (with approximate F distribution) or the large-sample Chisquared statistic (with asymptotic Chi-squared distribution). For a multivariate linear model, the multivariate test statistic to report — one or more of "Pillai",

"Wilks", "Hotelling-Lawley", or "Roy", with "Pillai" as the default.

idata

icontrasts

Ρ

title an optional character string to label the output.

V inverse of sum of squares and products of the model matrix; if missing it is

computed from the model.

vcov. a function for estimating the covariance matrix of the regression coefficients,

e.g., hccm, or an estimated covariance matrix for model. See also white.adjust. For the "lmList" and "nlsList" methods, vcov. must be a function (default-

ing to vcov) to be applied to each model in the list.

coef. a vector of coefficient estimates. The default is to get the coefficient estimates

from the model argument, but the user can input any vector of the correct length. For the "lmList" and "nlsList" methods, coef. must be a function (default-

ing to coef) to be applied to each model in the list.

white.adjust logical or character. Convenience interface to hccm (instead of using the argu-

ment vcov.). Can be set either to a character value specifying the type argument of hccm or TRUE, in which case "hc3" is used implicitly. The default is FALSE.

verbose If TRUE, the hypothesis matrix, right-hand-side vector (or matrix), and estimated

value of the hypothesis are printed to standard output; if FALSE (the default), the hypothesis is only printed in symbolic form and the value of the hypothesis is

not printed.

x an object produced by linearHypothesis.mlm.

SSP if TRUE (the default), print the sum-of-squares and cross-products matrix for the

hypothesis and the response-transformation matrix.

digits minimum number of signficiant digits to print.

pattern a regular expression to be matched against coefficient names.

suppress.vcov.msg

for internal use by methods that call the default method.

... arguments to pass down.

Details

linearHypothesis computes either a finite-sample F statistic or asymptotic Chi-squared statistic for carrying out a Wald-test-based comparison between a model and a linearly restricted model. The default method will work with any model object for which the coefficient vector can be retrieved by coef and the coefficient-covariance matrix by vcov (otherwise the argument vcov. has to be set explicitly). For computing the F statistic (but not the Chi-squared statistic) a df.residual method needs to be available. If a formula method exists, it is used for pretty printing.

The method for "lm" objects calls the default method, but it changes the default test to "F", supports the convenience argument white.adjust (for backwards compatibility), and enhances the output by the residual sums of squares. For "glm" objects just the default method is called (bypassing the "lm" method). The svyglm method also calls the default method.

The function 1ht also dispatches to linear Hypothesis.

The hypothesis matrix can be supplied as a numeric matrix (or vector), the rows of which specify linear combinations of the model coefficients, which are tested equal to the corresponding entries in the right-hand-side vector, which defaults to a vector of zeroes.

Alternatively, the hypothesis can be specified symbolically as a character vector with one or more elements, each of which gives either a linear combination of coefficients, or a linear equation in the

coefficients (i.e., with both a left and right side separated by an equals sign). Components of a linear expression or linear equation can consist of numeric constants, or numeric constants multiplying coefficient names (in which case the number precedes the coefficient, and may be separated from it by spaces or an asterisk); constants of 1 or -1 may be omitted. Spaces are always optional. Components are separated by plus or minus signs. Newlines or tabs in hypotheses will be treated as spaces. See the examples below.

If the user sets the arguments coef. and vcov., then the computations are done without reference to the model argument. This is like assuming that coef. is normally distibuted with estimated variance vcov. and the linearHypothesis will compute tests on the mean vector for coef., without actually using the model argument.

A linear hypothesis for a multivariate linear model (i.e., an object of class "mlm") can optionally include an intra-subject transformation matrix for a repeated-measures design. If the intra-subject transformation is absent (the default), the multivariate test concerns all of the corresponding coefficients for the response variables. There are two ways to specify the transformation matrix for the repeated measures:

- 1. The transformation matrix can be specified directly via the P argument.
- 2. A data frame can be provided defining the repeated-measures factor or factors via idata, with default contrasts given by the icontrasts argument. An intra-subject model-matrix is generated from the one-sided formula specified by the idesign argument; columns of the model matrix corresponding to different terms in the intra-subject model must be orthogonal (as is insured by the default contrasts). Note that the contrasts given in icontrasts can be overridden by assigning specific contrasts to the factors in idata. The repeated-measures transformation matrix consists of the columns of the intra-subject model matrix corresponding to the term or terms in iterms. In most instances, this will be the simpler approach, and indeed, most tests of interests can be generated automatically via the Anova function.

matchCoefs is a convenience function that can sometimes help in formulating hypotheses; for example matchCoefs(mod,":") will return the names of all interaction coefficients in the model mod.

Value

For a univariate model, an object of class "anova" which contains the residual degrees of freedom in the model, the difference in degrees of freedom, Wald statistic (either "F" or "Chisq"), and corresponding p value. The value of the linear hypothesis and its covariance matrix are returned respectively as "value" and "vcov" attributes of the object (but not printed).

For a multivariate linear model, an object of class "linearHypothesis.mlm", which contains sums-of-squares-and-product matrices for the hypothesis and for error, degrees of freedom for the hypothesis and error, and some other information.

The returned object normally would be printed.

logit 81

Description

Compute the logit transformation of proportions or percentages.

Usage

```
logit(p, percents=range.p[2] > 1, adjust)
```

Arguments

p numeric vector or array of proportions or percentages.

percents TRUE for percentages.

adjust adjustment factor to avoid proportions of 0 or 1; defaults to 0 if there are no such

proportions in the data, and to .025 if there are.

Details

Computes the logit transformation logit = $\log[p/(1-p)]$ for the proportion p.

If p = 0 or 1, then the logit is undefined. logit can remap the proportions to the interval (adjust, 1 -adjust) prior to the transformation. If it adjusts the data automatically, logit will print a warning message.

Value

a numeric vector or array of the same shape and size as p.

mcPlots

Draw Linear Model Marginal and Conditional Plots in Parallel or Overlaid

Description

the mcPlot function draws two graphs or overlays the two graphs. For a response Y and a regressor X, the first plot is the marginal plot of Y versus X with both variables centered, visualizing the conditional distribution of Y given X ignoring all other regressors. The second plot is an added-variable for X after all other regressors, visualizing the conditional distribution of Y given X after adjusting for all other predictors. The added variable plot by default is drawn using the same xlim and ylim as the centered marginal plot to emphasize that conditioning removes variation in both the regressor and the response. The plot is primarily intended as a pedagogical tool for understanding coefficients in first-order models.

Usage

mcPlots 83

Arguments

model bject produced by lm; the "glm" method just reports an error.

terms A one-sided formula that specifies a subset of the predictors. One added-variable

plot is drawn for each regressor and for each basis vector used to define a factor. For example, the specification terms = $^{\sim}$. $^{\sim}$ X3 would plot against all terms except for X3. If this argument is a quoted name of one of the regressors or factors, the added-variable plot is drawn for that regressor or factor only. Unlike other car functions, the formula should include the names of regressors, not predictors. That is, if $\log(X4)$ is used to represent a predictor X4, the formula should

specify terms = $\sim \log(X4)$.

variable A quoted string giving the name of a numeric predictor in the model matrix for

the horizontal axis. To plot against a factor, you need to specify the full name of one of the indicator variables that define the factor. For example, for a factor called type with levels A, B and C, using the usual drop-first level parameterization of the factor, the regressors for type would be typeB or typeC. Similarly, to plot against the regressor log(X4), you must specify "log((X4)", not "X4".

layout If set to a value like c(1,2) or c(6,2), the layout of the graph will have this

many rows and columns. If not set, behavior depends on the value of the

overlaid argument; see the details

ask If TRUE, ask the user before drawing the next plot; if FALSE don't ask.

... mcPlots passes these arguments to mcPlot. mcPlot passes arguments to plot.

id controls point identification; if FALSE (the default), no points are identified; can

be a list of named arguments to the showLabels function; TRUE is equivalent to

list(method=list(abs(residuals(model,type="pearson")),"x"), n=2, cex=1, col=carPalette(method=list(abs(residuals(model,type="pearson")),"x"), n=2, cex=1, col=carPalette(method=list(abs(residuals(model(model(type="pearson"))),"x"), n=2, cex=1, col=carPalette(method=list(abs(residuals(model(model(type="pearson"))),"x"), n=2, cex=1, col=carPalette(method=list(abs(residuals(model(model(model(type="pearson"))),"x"), n=2, cex=1, col=carPalette(method=list(abs(residuals(model(model(type="pearson"))),"x"), n=2, cex=1, col=carPalette(method=list(abs(residuals(model(model(model(type="pearson"))),"x"), n=2, cex=1, col=carPalette(model(mode

which identifies the 2 points with the largest residuals and the 2 points with the

most extreme horizontal (X) values.

overlaid If TRUE, the default, overlay the marginal and conditional plots on the same

graph; otherwise plot them side-by-side. See the details below

col.marginal, col.conditional

colors for points, lines, ellipses in the marginal and conditional plots, respec-

tively. The defaults are determined by the carPalette function.

col.arrows color for the arrows with overlaid=TRUE

pch Plotting character for marginal and conditional plots, respectively.

cex size of plotted points; default is taken from par("cex").

pt.wts if TRUE (the default is FALSE), the areas of plotted points for a weighted least

squares fit are made proportional to the weights, with the average size taken

from the cex argument.

lwd line width; default is 2 (see par).

grid If TRUE, the default, a light-gray background grid is put on the graph.

ellipse Arguments to pass to the dataEllipse function, in the form of a list with named

elements; e.g., ellipse.args=list(robust=TRUE)) will cause the ellipse to be plotted using a robust covariance-matrix. if FALSE, the default, no ellipse is plotted. TRUE is equivalent to ellipse=list(levels=0.5), which plots a

bivariate-normal 50 percent concentration ellipse.

84 mcPlots

new if TRUE, the default, the plot window is reset when overlaid=FALSE using

par{mfrow=c(1,2)}. If FALSE, the layout of the plot window is not reset. Users

will ordinarily ignore this argument.

title If TRUE, the default, the standard main argument in plot is used to add a stan-

dard title to each plot. If FALSE no title is used.

Details

With an 1m object, suppose the response is Y, X is a numeric regressor of interest, and Z is all the remaining predictors, possibly including interactions and factors. This function produces two graphs. The first graph is the marginal plot of Y versus X, with each variable centered around its mean. The second conditional plot is the added-variable plot of e(Y|Z) versus e(X|Z) where e(a|b) means the Pearson residuals from the regression of a on b. If overlaid=TRUE, these two plots are overlaid in one graph, with the points in different colors. In addition, each point in the marginal plot is joined to its value in the conditional plot by an arrow. Least squares regression lines fit to the marginal and conditional graphs are also shown; data ellipsoids can also be added. If overlaid=FALSE, then the two graphs are shown in side-by-side plots as long as the second argument to layout is equal to 2, or layout is set by the function. The arrows are omitted if the graphs are not overlaid.

These graphs are primarily for teaching, as the marginal plot shows the relationship between Y and X ignoring Z, while the conditional is the relationship between Y and X given X. By keeping the scales the same in both graphs the effect of conditioning on both X and Y can be visualized.

This function is intended for first-order models with numeric predictors only. For a factor, one (pair) of mcPlots will be produced for each of the dummy variables in the basis for the factor, and the resulting plots are not generally meaningful because they depend on parameterization. If the mean function includes interactions, then mcPlots for main effects may violate the hierarchy principle, and may also be of little interest. mcPlots for interactions of numerical predictors, however, can be useful.

These graphs are closely related to the ARES plots proposed by Cook and Weisberg (1989). This plot would benefit from animation.

Value

These functions are used for their side effect of producing plots.

mmps

Marginal Model Plotting

Description

For a regression object, draw a plot of the response on the vertical axis versus a linear combination u of regressors in the mean function on the horizontal axis. Added to the plot are a smooth for the graph, along with a smooth from the plot of the fitted values on u. mmps is an alias for marginalModelPlots, and mmp is an alias for marginalModelPlot.

Usage

        main, groups, key=TRUE, ...)
marginalModelPlot(...)
mmp(model, ...)
## S3 method for class 'lm'
mmp(model, variable, sd = FALSE,
    xlab = deparse(substitute(variable)),
    smooth=TRUE, key=TRUE, pch, groups=NULL, ...)
## Default S3 method:
mmp(model, variable, sd = FALSE,
    xlab = deparse(substitute(variable)), ylab, smooth=TRUE,
    key=TRUE, pch, groups=NULL,
    col.line = carPalette()[c(2, 8)], col=carPalette()[1],
    id=FALSE, grid=TRUE, ...)
## S3 method for class 'glm'
mmp(model, variable, sd = FALSE,
    xlab = deparse(substitute(variable)), ylab,
    smooth=TRUE, key=TRUE, pch, groups=NULL,
    col.line = carPalette()[c(2, 8)], col=carPalette()[1],
    id=FALSE, grid=TRUE, ...)
```

86 mmps

Arguments

sd

model A regression object, usually of class either 1m or g1m, for which there is a

predict method defined.

terms A one-sided formula. A marginal model plot will be drawn for each term on the

right-side of this formula that is not a factor. The default is \sim ., which specifies that all the terms in formula(object) will be used. If a conditioning argument is given, eg terms = \sim . | a, then separate colors and smoothers are used for each

unique non-missing value of a. See examples below.

fitted If TRUE, the default, then a marginal model plot in the direction of the fitted values for a linear model or the linear predictor of a generalized linear model

will be drawn.

layout If set to a value like c(1,1) or c(4,3), the layout of the graph will have this

many rows and columns. If not set, the program will select an appropriate layout. If the number of graphs exceed nine, you must select the layout yourself, or you will get a maximum of nine per page. If layout=NA, the function does not set the layout and the user can use the par function to control the layout, for example

to have plots from two models in the same graphics window.

ask If TRUE, ask before clearing the graph window to draw more plots.

main Main title for the array of plots. Use main="" to suppress the title; if missing, a

title will be supplied.

Additional arguments passed from mmps to mmp and then to plot. Users should

generally use mmps, or equivalently marginal Model Plots.

variable The quantity to be plotted on the horizontal axis. If this argument is missing,

the horizontal variable is the linear predictor, returned by predict(object) for models of class lm, with default label "Fitted values", or returned by predict(object,type="link") for models of class glm, with default label "Linear predictor". It can be any other vector of length equal to the number of observations in the object. Thus the mmp function can be used to get a marginal model plot versus any regressor or predictor while the mmps function can be used only to get marginal model plots for the first-order regressors in the formula. In particular, terms defined by a spline basis are skipped by mmps, but

you can use mmp to get the plot for the variable used to define the splines.

If TRUE, display sd smooths. For a binomial regression with all sample sizes equal to one, this argument is ignored as the SD bounds don't make any sense.

xlab label for horizontal axis.

ylab label for vertical axis, defaults to name of response.

smooth specifies the smoother to be used along with its arguments; if FALSE, no smoother

is shown; can be a list giving the smoother function and its named arguments; TRUE, the default, is equivalent to list(smoother=loessLine, span=2/3) for linear models and list(smoother=gamLine, k=3) for generalized linear models. See ScatterplotSmoothers for the smoothers supplied by the car package and their arguments; the spread argument is not supported for marginal model

plots.

groups The name of a vector that specifies a grouping variable for separate colors/smoothers.

This can also be specified as a conditioning argument on the terms argument.

mmps 87

key	If TRUE, include a key at the top of the plot, if FALSE omit the key. If grouping is present, the key is only printed for the upper-left plot.
id	controls point identification; if FALSE (the default), no points are identified; can be a list of named arguments to the showLabels function; TRUE is equivalent to list(method="y",n=2,cex=1,col=carPalette()[1],location="lr"), which identifies the 2 points with the most unusual response (Y) values.
pch	plotting character to use if no grouping is present.
col.line	colors for data and model smooth, respectively. The default is to use carPalette, $carPalette()[c(2,8)]$, blue and red.
col	color(s) for the plotted points.
grid	If TRUE, the default, a light-gray background grid is put on the graph

Details

mmp and marginalModelPlot draw one marginal model plot against whatever is specified as the horizontal axis. mmps and marginalModelPlots draws marginal model plots versus each of the terms in the terms argument and versus fitted values. mmps skips factors and interactions if they are specified in the terms argument. Terms based on polynomials or on splines (or potentially any term that is represented by a matrix of regressors) will be used to form a marginal model plot by returning a linear combination of the terms. For example, if you specify terms = $\sim X1 + \text{poly}(X2,3)$ and poly(X2,3) was part of the original model formula, the horizontal axis of the marginal model plot for X2 will be the value of predict(model,type="terms")[,"poly(X2,3)"]). If the predict method for the model you are using doesn't support type="terms", then the polynomial/spline term is skipped. Adding a conditioning variable, e.g., terms = \sim a + b | c, will produce marginal model plots for a and b with different colors and smoothers for each unique non-missing value of c.

For linear models, the default smoother is loess. For generalized linear models, the default smoother uses gamLine, fitting a generalized additive model with the same family, link and weights as the fit of the model. SD smooths are not computed for for generalized linear models.

For generalized linear models the default number of elements in the spline basis is k=3; this is done to allow fitting for predictors with just a few support points. If you have many support points you may wish to set k to a higher number, or k=-1 for the default used by gam.

Value

Used for its side effect of producing plots.

```

ncvTest

Score Test for Non-Constant Error Variance

Description

Computes a score test of the hypothesis of constant error variance against the alternative that the error variance changes with the level of the response (fitted values), or with a linear combination of predictors.

Usage

```
ncvTest(model, ...)
## S3 method for class 'lm'
ncvTest(model, var.formula, ...)
## S3 method for class 'glm'
ncvTest(model, ...) # to report an error
```

Arguments

model a weighted or unweighted linear model, produced by lm.

var.formula a one-sided formula for the error variance; if omitted, the error variance depends on the fitted values.

... arguments passed down to methods functions; not currently used.

outlierTest 89

Details

This test is often called the Breusch-Pagan test; it was independently suggested with some extension by Cook and Weisberg (1983).

ncvTest.glm is a dummy function to generate an error when a glm model is used.

Value

The function returns a chisqTest object, which is usually just printed.

outlierTest

Bonferroni Outlier Test

Description

Reports the Bonferroni p-values for testing each observation in turn to be a mean-shift outlier, based Studentized residuals in linear (t-tests), generalized linear models (normal tests), and linear mixed models.

90 outlierTest

Usage

```
outlierTest(model, ...)
## S3 method for class 'lm'
outlierTest(model, cutoff=0.05, n.max=10, order=TRUE,
labels=names(rstudent), ...)
## S3 method for class 'lmerMod'
outlierTest(model, ...)
## S3 method for class 'outlierTest'
print(x, digits=5, ...)
```

Arguments

model	an lm, glm, or lmerMod model object; the "lmerMod" method calls the "lm" method and can take the same arguments.
cutoff	observations with Bonferroni p-values exceeding cutoff are not reported, unless no observations are nominated, in which case the one with the largest Studentized residual is reported.
n.max	maximum number of observations to report (default, 10).
order	$report\ Studenized\ residuals\ in\ descending\ order\ of\ magnitude?\ (default,\ TRUE).$
labels	an optional vector of observation names.
	arguments passed down to methods functions.
x	outlierTest object.
digits	number of digits for reported p-values.

Details

For a linear model, p-values reported use the t distribution with degrees of freedom one less than the residual df for the model. For a generalized linear model, p-values are based on the standard-normal distribution. The Bonferroni adjustment multiplies the usual two-sided p-value by the number of observations. The lm method works for glm objects. To show all of the observations set cutoff=Inf and n.max=Inf.

Value

an object of class outlierTest, which is normally just printed.

panel.car

Panel Function for Coplots

Description

a panel function for use with coplot that plots points, a lowess line, and a regression line.

Usage

```
panel.car(x, y, col, pch, cex=1, span=0.5, lwd=2,
  reg.line=lm, lowess.line=TRUE, ...)
```

Arguments

X	vector giving horizontal coordinates.
V	vector giving vertical coordinates.

col point color.

pch plotting character for points.

cex character expansion factor for points.

span span for lowess smoother.

lwd line width, default is 2.

reg.line function to compute coefficients of regression line, or FALSE for no line.

lowess.line if TRUE plot lowess smooth.

... other arguments to pass to functions lines and regLine.

Value

NULL. This function is used for its side effect: producing a panel in a coplot.

poTest

Test for Proportional Odds in the Proportional-Odds Logistic-Regression Model

Description

The poTest function implements tests proposed by Brant (1990) for proportional odds for logistic models fit by the polr function in the MASS package.

Usage

```
poTest(model, ...)
## S3 method for class 'polr'
poTest(model, ...)
## S3 method for class 'poTest'
print(x, digits=3, ...)
```

Arguments

```
model a proptional-odds logit model fit by polr.

x an object produced by poTest.

digits number of significant digits to print.

... ignored.
```

Value

poTest returns an object meant to be printed showing the results of the tests.

}</pre>
```

powerTransform

Finding Univariate or Multivariate Power Transformations

Description

powerTransform uses the maximum likelihood-like approach of Box and Cox (1964) to select a transformation of a univariate or multivariate response for normality, linearity and/or constant variance. Available families of transformations are the default Box-Cox power family and two additioal families that are modifications of the Box-Cox family that allow for (a few) negative responses. The summary method automatically computes two or three likelihood ratio type tests concerning the transformation powers.

Usage

```
powerTransform(object, ...)
## Default S3 method:
powerTransform(object, family="bcPower", ...)
## S3 method for class 'lm'
powerTransform(object, family="bcPower", ...)
## S3 method for class 'formula'
powerTransform(object, data, subset, weights, na.action, family="bcPower", ...)
## S3 method for class 'lmerMod'
powerTransform(object, family="bcPower", ...)
```

Arguments

object

This can either be an object of class 1m or 1merMod, a formula, or a matrix or vector; see below.

family

The quoted name of a family of transformations. The available options are "bcPower" for the default for the Box-Cox power family; "bcnPower" for a two-parameter modification of the Box-Cox family that allows negative responses (Hawkins and Weisberg (2017)), and the "yjPower" family (Yeo and Johnson(2000)), another modifiation of the Box-Cox family that allows a few negative values. All three families are documented at bcPower.

data A data frame or environment, as in 'lm'.

subset Case indices to be used, as in 'lm'.

weights Weights as in 'lm'.

na.action Missing value action, as in 'lm'.

... Additional arguments that used in the interative algorithm; defaults are generally

adequate. For use with the bcnPower family, a convergence criterion can be set with conv=.0001 the default, and a minimum positive value of the location

parameter can be set, with default gamma.min=.1.

Details

This function implements the Box and Cox (1964) method of selecting a power transformation of a variable toward normality, and its generalization by Velilla (1993) to a multivariate response. Cook and Weisberg (1999) and Weisberg (2014) suggest the usefulness of transforming a set of predictors z1,z2,z3 for multivariate normality. It also includes two additional families that allow for negative values.

If the object argument is of class 'lm' or 'lmerMod', the Box-Cox procedure is applied to the conditional distribution of the response given the predictors. For 'lm' objects, the respose may be multivariate, and each column will have its own transformation. With 'lmerMod' the response must be univariate.

The object argument may also be a formula. For example, $z \sim x1 + x2 + x3$ will estimate a transformation for the response z from a family after fitting a linear model with the given formula. cbind(y1,y2,y3) ~ 1 specifies transformations to multivariate normality with no predictors. A vector value for object, for example powerTransform(ais\$LBM), is equivalent topowerTransform(LBM ~ 1,ais). Similarly, powerTransform(cbind(ais\$LBM,ais\$SSF)), where the first argument is a matrix rather than a formula is equivalent to specification of a mulitvariate linear model powerTransform(cbind(LBM,SSF) ~ 1,ais).

Three families of power transformations are available. The default Box-Cox power family (family="bcPower") of power transformations effectively replaces a vector by that vector raised to a power, generally in the range from -3 to 3. For powers close to zero, the log-transformation is suggested. In practical situations, after estimating a power using the powerTransform function, a variable would be replaced by a simple power transformation of it, for example, if $\lambda \approx 0.5$, then the correspoding variable would be replaced by its square root; if λ is close enough to zero, the the variable would be replaced by its natural logarithm. The Box-Cox family requires the responses to be strictly positive.

The family="bcnPower", or Box-Cox with negatives, family proposed by Hawkins and Weisberg (2017) allows for (a few) non-positive values, while allowing for the transformed data to be interpreted similarly to the interpretation of Box-Cox transformed values. This family is the Box-Cox transformation of $z=.5*(y+(y^2+\gamma^2)^{1/2})$ that depends on a location parameter γ . The quantity z is positive for all values of y. If $\gamma=0$ and y is strictly positive, then the Box-Cox and the bcnPower transformations are identical. When fitting the Box-Cox with negatives family, lambda is restricted to the range [-3, 3], and gamma is restricted to the range from gamma.min=.1 to the largest positive value of the variable, since values outside these ranges are unreasonable in practice. The value of gamma.min can be changed with an argument to powerTransform.

The final family="yjPower" uses the Yeo-Johnson transformation, which is the Box-Cox transformation of U+1 for nonnegative values, and of |U|+1 with parameter $2-\lambda$ for U negative and thus it provides a family for fitting when (a few) observations are negative. Because of the

unusual constraints on the powers for positive and negative data, this transformation is not used very often, as results are difficult to interpret. In practical problems, a variable would be replaced by its Yeo-Johnson transformation computed using the yjPower function.

The function testTransform is used to obtain likelihood ratio tests for any specified value for the transformation parameter(s).

Computations maximize the likelihood-like functions described by Box and Cox (1964) and by Velilla (1993). For univariate responses, the computations are very stable and problems are unlikely, although for 'lmer' models computations may be very slow because the model is refit many times. For multivariate responses with the bcnPower family, the computing algorithm may fail. In this case we recommend adding the argument itmax = 1 to the call to powerTransform. This will return the starting value estimates of the transformation parameters, fitting a d-dimensional response as if all the d responses were independent.

Value

An object of class powerTransform or class bcnPowerTransform if family="bcnPower" that inherits from powerTransform is returned, including the components listed below.

A summary method presents estimated values for the transformation power lambda and for the 'bcnPower' family the location parameter gamma as well. Standard errors and Wald 95% confidence intervals based on the standard errors are computed from the inverse of the sample Hessian matrix evaluted at the estimates. The interval estimates for the gamma parameters will generally be very wide, reflecting little information available about the location parameter. Likelihood ratio type tests are also provided. For the 'bcnPower' family these are based on the profile loglikelihood for lambda alone; that is, we treat gamma as a nusiance parameter and average over it.

The components of the returned object includes

lambda Estimated transformation parameter

roundlam Convenient rounded values for the estimates. These rounded values will usually

be the desired transformations.

gamma Estimated location parameters for bcnPower, NULL otherwise invHess Estimated covariance matrix of the estimated parameters

11ik Value of the log-likelihood at the estimates

The summary method for powerTransform returns an array with columns labeled "Est Power" for the value of lambda that maximizes the likelihood; "Rounded Pwr" for roundlam, and columns "Wald Lwr Bnd" and "Wald Ur Bnd" for a 95 percent Wald normal theory confidence interval for lambda computed as the estimate plus or minus 1.96 times the standard error.

Predict

Model Predictions

Description

Predict is a generic function with, at present, a single method for "lm" objects, Predict.lm, which is a modification of the standard predict.lm method in the stats package, but with an additional vcov. argument for a user-specified covariance matrix for intreval estimation.

Usage

```
Predict(object, ...)
## S3 method for class 'lm'
Predict(object, newdata, se.fit = FALSE,
    scale = NULL, df = Inf,
    interval = c("none", "confidence", "prediction"),
    level = 0.95, type = c("response", "terms"),
    terms = NULL, na.action = na.pass,
    pred.var = res.var/weights, weights = 1, vcov., ...)
```

Arguments

```
object a model object for which predictions are desired.

newdata, se.fit, scale, df, interval, level, type, terms, na.action, pred.var, weights see predict.lm.

vcov. optional, either a function to compute the coefficient covariance matrix of object (e.g., hccm) or a coefficient covariance matrix (as returned, e.g., by hccm). To use a bootstrap to estimate the covariance matrix, set vcov. = vcov(Boot(object)).

... arguments to pass down to Predict or predict methods.
```

98 qqPlot

Details

If there is no appropriate method for Predict, then a predict method is invoked. If there is a *specific* predict method for the primary class of object but only an *inherited* Predict method, then the predict method is invoked. Thus an object of class c("glm", "lm") will invoke method predict.glm rather than Predict.lm, but an object of class c("aov", "lm") will invoke Predict.lm rather than predict.lm.

Value

```
See predict and predict.lm.

p2 <- Predict(mod, newd, interval="prediction", vcov.=vcov)
all.equal(p1, p2) # the same

(predict(mod, newd, se=TRUE))
(p3 <- Predict(mod, newd, se=TRUE, vcov.=hccm)) # larger SEs
p4 <- Predict(mod, newd, se=TRUE, vcov.=hccm(mod, type="hc3"))
all.equal(p3, p4) # the same</pre>
```

qqPlot

Quantile-Comparison Plot

Description

Plots empirical quantiles of a variable, or of studentized residuals from a linear model, against theoretical quantiles of a comparison distribution. Includes options not available in the qqnorm function.

qqPlot 99

Usage

```
qqPlot(x, ...)
qqp(...)
## Default S3 method:
qqPlot(x, distribution="norm", groups, layout,
   ylim=range(x, na.rm=TRUE), ylab=deparse(substitute(x)),
   xlab=paste(distribution, "quantiles"), glab=deparse(substitute(groups)),
   main=NULL, las=par("las"),
   envelope=TRUE, col=carPalette()[1], col.lines=carPalette()[2],
   lwd=2, pch=1, cex=par("cex"),
   line=c("quartiles", "robust", "none"), id=TRUE, grid=TRUE, ...)
## S3 method for class 'formula'
qqPlot(formula, data, subset, id=TRUE, ylab, glab, ...)
## S3 method for class 'lm'
qqPlot(x, xlab=paste(distribution, "Quantiles"),
   ylab=paste("Studentized Residuals(",
                deparse(substitute(x)), ")", sep=""),
   main=NULL, distribution=c("t", "norm"),
   line=c("robust", "quartiles", "none"), las=par("las"),
   simulate=TRUE, envelope=TRUE, reps=100,
   col=carPalette()[1], col.lines=carPalette()[2], lwd=2, pch=1, cex=par("cex"),
    id=TRUE, grid=TRUE, ...)
```

Arguments

x vector of numeric values or 1m object.

distribution root name of comparison distribution – e.g., "norm" for the normal distribution;

t for the t-distribution.

groups an optional factor; if specified, a QQ plot will be drawn for x within each level

of groups.

layout a 2-vector with the number of rows and columns for plotting by groups – for

example c(1,3) for 1 row and 3 columns; if omitted, the number of rows and columns will be selected automatically; the specified number of rows and columns must be sufficient to accommodate the number of groups; ignored if there

is no grouping factor.

formula one-sided formula specifying a single variable to be plotted or a two-sided for-

mula of the form variable \sim factor, where a QQ plot will be drawn for variable

within each level of factor.

data optional data frame within which to evaluage the formula.

subset optional subset expression to select cases to plot.

ylim limits for vertical axis; defaults to the range of x. If plotting by groups, a com-

mon y-axis is used for all groups.

100 qqPlot

yıab	label for vertical (empirical quantiles) axis.
xlab	label for horizontal (comparison quantiles) axis.
σlah	label for the grouping variable

glab label for the grouping variable

main label for plot.

envelope TRUE (the default), FALSE, a confidence level such as 0.95, or a list specifying

how to plot a point-wise confidence envelope (see Details).

las if 0, ticks labels are drawn parallel to the axis; set to 1 for horizontal labels (see

par).

col color for points; the default is the *first* entry in the current **car** palette (see

carPalette and par).

col. lines color for lines; the default is the *second* entry in the current **car** palette.

pch plotting character for points; default is 1 (a circle, see par).

cex factor for expanding the size of plotted symbols; the default is 1.

id controls point identification; if FALSE, no points are identified; can be a list of

named arguments to the showLabels function; TRUE is equivalent to list(method="y", n=2, cex=1, col=

which identifies the 2 points with the 2 points with the most extreme verical values — studentized residuals for the "1m" method. Points labels are by default taken from the names of the variable being plotted is any, else case indices are used. Unlike most graphical functions in **car**, the default is id=TRUE to include

point identification.

lwd line width; default is 2 (see par).

line "quartiles" to pass a line through the quartile-pairs, or "robust" for a robust-

regression line; the latter uses the rlm function in the MASS package. Specifying

line = "none" suppresses the line.

simulate if TRUE calculate confidence envelope by parametric bootstrap; for 1m object

only. The method is due to Atkinson (1985).

reps integer; number of bootstrap replications for confidence envelope.
... arguments such as df to be passed to the appropriate quantile function.

grid If TRUE, the default, a light-gray background grid is put on the graph

Details

Draws theoretical quantile-comparison plots for variables and for studentized residuals from a linear model. A comparison line is drawn on the plot either through the quartiles of the two distributions, or by robust regression.

Any distribution for which quantile and density functions exist in R (with prefixes q and d, respectively) may be used. When plotting a vector, the confidence envelope is based on the SEs of the order statistics of an independent random sample from the comparison distribution (see Fox, 2016). Studentized residuals from linear models are plotted against the appropriate t-distribution with a point-wise confidence envelope computed by default by a parametric bootstrap, as described by Atkinson (1985). The function qqp is an abbreviation for qqPlot.

The envelope argument can take a list with the following named elements; if an element is missing, then the default value is used:

recode 101

```
level confidence level (default 0.95).
style one of "filled" (the default), "lines", or "none".
col color (default is the value of col.lines).
alpha transparency/opacity of a filled confidence envelope, a number between 0 and 1 (default 0.15).
border controls whether a border is drawn around a filled confidence envelope (default TRUE).
```

Value

These functions return the labels of identified points, unless a grouping factor is employed, in which case NULL is returned invisibly.

recode

Recode a Variable

Description

Recodes a numeric vector, character vector, or factor according to simple recode specifications. Recode is an alias for recode that avoids name clashes with packages, such as **Hmisc**, that have a recode function.

102 recode

Usage

```
recode(var, recodes, as.factor, as.numeric=TRUE, levels)
Recode(...)
```

Arguments

var numeric vector, character vector, or factor.

recodes character string of recode specifications: see below.

as.factor return a factor; default is TRUE if var is a factor, FALSE otherwise.

as.numeric if TRUE (the default), and as.factor is FALSE, then the result will be coerced to

numeric if all values in the result are numerals—i.e., represent numbers.

levels an optional argument specifying the order of the levels in the returned factor; the

default is to use the sort order of the level names.

... arguments to be passed to recode.

Details

Recode specifications appear in a character string, separated by semicolons (see the examples below), of the form input=output. If an input value satisfies more than one specification, then the first (from left to right) applies. If no specification is satisfied, then the input value is carried over to the result. NA is allowed on input and output. Several recode specifications are supported:

single value For example, 0=NA.

vector of values For example, c(7,8,9)='high'.

range of values For example, 7:9='C'. The special values 10 and hi may appear in a range. For example, 10:10=1. *Note:* : is *not* the R sequence operator. In addition, you may not use : with the c function within a recode specification, so for example c(1,3,5:7) will cause an error.

else everything that does not fit a previous specification. For example, else=NA. Note that else matches *all* otherwise unspecified values on input, including NA.

Character data and factor levels on the left-hand side of a recode specification must be quoted. Thus, e.g., c(a,b,c) = 'low' is not allowed, and should be c('a','b','c') = 'low'. Similarly, the colon is reserved for numeric data, and, e.g., c('a':'c') = 'low' is not allowed. If the var argument is a character variable with (some) values that are composed of numerals, or a factor with (some) levels that are numerals (e.g., '12' or '-2'), then these too must be quoted and cannot be used with colons (e.g., '15':'19' = '15 to 19' is not allowed, and could be specified as c('15','16','17','18','19') = '15 to 19', assuming that all values are the character representation of whole numbers).

If all of the output values are numeric, and if as. factor is FALSE, then a numeric result is returned; if var is a factor, then by default so is the result.

Value

a recoded vector of the same length as var.

Recode(x, "1:2='A'; 3='B'")
## [1] "A" "A" "B" "A" "A" "B" "A" "B" "A" "B"</pre>
```

regLine

Plot Regression Line

Description

Plots a regression line on a scatterplot; the line is plotted between the minimum and maximum x-values.

Usage

```
regLine(mod, col=carPalette()[2], lwd=2, lty=1,...)
```

Arguments

mod	a model, such as produced by 1m, that responds to the coef function by returning a 2-element vector, whose elements are interpreted respectively as the intercept and slope of a regresison line.
col	color for points and lines; the default is the <i>second</i> entry in the current car palette (see carPalette and par).
lwd	line width; default is 2 (see par).
lty	line type; default is 1, a solid line (see par).
	optional arguments to be passed to the lines plotting function.

Details

In contrast to abline, this function plots only over the range of the observed x-values. The x-values are extracted from mod as the second column of the model matrix.

Value

NULL. This function is used for its side effect: adding a line to the plot.

regLine(lm(repwt~weight, subset=sex=="M", data=Davis))
regLine(lm(repwt~weight, subset=sex=="F", data=Davis), lty=2)
```

residualPlots

Residual Plots for Linear and Generalized Linear Models

Description

Plots the residuals versus each term in a mean function and versus fitted values. Also computes a curvature test for each of the plots by adding a quadratic term and testing the quadratic to be zero. For linear models, this is Tukey's test for nonadditivity when plotting against fitted values.

Usage

```
### residualPlots calls residualPlot, so these arguments can be
### used with either function
residualPlot(model, ...)
## Default S3 method:
residualPlot(model, variable = "fitted", type = "pearson",
     groups, plot = TRUE, linear = TRUE,
     quadratic = if(missing(groups)) TRUE else FALSE,
     smooth=FALSE, id=FALSE,
     col = carPalette()[1], col.quad = carPalette()[2], pch=1,
     xlab, ylab, lwd = 1, lty = 1,
     grid=TRUE, key=!missing(groups), ...)
## S3 method for class 'lm'
residualPlot(model, ...)
## S3 method for class 'glm'
residualPlot(model, variable = "fitted", type = "pearson",
    plot = TRUE, quadratic = FALSE, smooth=TRUE, ...)
```

Arguments

model

A regression object.

terms

A one-sided formula that specifies a subset of the factors and the regressors that appear in the formula that defined the model. The default \sim . is to plot against all first-order terms, both regressors and factors. Higher order terms are skipped. For example, the specification terms = \sim . –X3 would plot against all regressors except for X3. To get a plot against fitted values only, use the arguments terms = \sim 1. Interactions are skipped. For polynomial terms, the plot is against the first-order variable (which may be centered and scaled depending on how the poly function is used). Plots against factors are boxplots. Plots against other matrix terms, like splines, use the result of predict(model), type="terms")[,variable]) as the horizontal axis; if the predict method doesn't permit this type, then matrix terms are skipped.

A grouping variable can also be specified in the terms, so, for example terms= \sim . | type would use the factor type to set a different color and symbol for each level of type. Any fits in the plots will also be done separately for each level of group.

layout

If set to a value like c(1,1) or c(4,3), the layout of the graph will have this many rows and columns. If not set, the program will select an appropriate layout. If the number of graphs exceed nine, you must select the layout yourself, or you will get a maximum of nine per page. If layout=NA, the function does not set the layout and the user can use the par function to control the layout, for example to have plots from two models in the same graphics window.

ask

If TRUE, ask the user before drawing the next plot; if FALSE, don't ask.

main

Main title for the graphs. The default is main="" for no title.

fitted If TRUE, the default, include the plot against fitted values. AsIs If FALSE, terms that use the "as-is" function I are skipped; if TRUE, the default, they are included. plot If TRUE, draw the plot(s). tests If TRUE, display the curvature tests. With glm's, the argument start is ignored in computing the curvature tests. Additional arguments passed to residualPlot and then to plot. Quoted variable name for the factor or regressor to be put on the horizontal axis, variable or the default "fitted" to plot versus fitted values. Type of residuals to be used. Pearson residuals are appropriate for 1m objects type since these are equivalent to ordinary residuals with ols and correctly weighted residuals with wls. Any quoted string that is an appropriate value of the type argument to residuals.lm or "rstudent" or "rstandard" for Studentized or standardized residuals. A grouping indicator. Points in different groups will be plotted with different groups colors and symbols. If missing, no grouping is used. In residualPlots, the grouping variable can also be set in the terms argument, as described above. The default is no grouping. If used, the groups argument shoud be a vector of values of the same length as the vector of residuals, for example groups = subject where subject indicates the grouping. If TRUE, adds a horizontal line at zero if no groups. With groups, display the linear within level of groups ols regression of the residuals as response and the horizontal axis as the regressor. quadratic if TRUE, fits the quadratic regression of the vertical axis on the horizontal axis and displays a lack of fit test. Default is TRUE for 1m and FALSE for g1m or if groups not missing. smooth specifies the smoother to be used along with its arguments; if FALSE, which is the default except for generalized linear models, no smoother is shown; can be a list giving the smoother function and its named arguments; TRUE is equivalent to list(smoother=loessLine, span=2/3, col=carPalette()[3]), which is the default for a GLM. See ScatterplotSmoothers for the smoothers supplied by the **car** package and their arguments. id controls point identification; if FALSE (the default), no points are identified; can be a list of named arguments to the showLabels function; TRUE is equivalent to list(method="r",n=2,cex=1,col=carPalette()[1],location="lr"), which identifies the 2 points with the largest absolute residuals. col default color for points. If groups is set, col can be a list at least as long as the number of levels for groups giving the colors for each groups. default color for quadratic fit if groups is missing. Ignored if groups are used. col.quad plotting character. The default is pch=1. If groups are used, pch can be set to a pch vector at least as long as the number of groups. xlab X-axis label. If not specified, a useful label is constructed by the function.

Y-axis label. If not specified, a useful label is constructed by the function.

ylab

lwd	line width for lines.
lty	line type for quadratic.
grid	If TRUE, the default, a light-gray background grid is put on the graph
key	Should a key be added to the plot? Default is !is.null(groups).

Details

residualPlots draws one or more residuals plots depending on the value of the terms and fitted arguments. If terms = $^{\sim}$., the default, then a plot is produced of residuals versus each first-order term in the formula used to create the model. Interaction terms, spline terms, and polynomial terms of more than one predictor are skipped. In addition terms that use the "as-is" function, e.g., I(X^2), will also be skipped unless you set the argument AsIs=TRUE. A plot of residuals versus fitted values is also included unless fitted=FALSE.

In addition to plots, a table of curvature tests is displayed. For plots against a term in the model formula, say X1, the test displayed is the t-test for for I(X1^2) in the fit of update,model,~. + I(X1^2)). Econometricians call this a specification test. For factors, the displayed plot is a boxplot, no curvature test is computed, and grouping is ignored. For fitted values in a linear model, the test is Tukey's one-degree-of-freedom test for nonadditivity. You can suppress the tests with the argument tests=FALSE. If grouping is used curvature tests are not displayed.

residualPlot, which is called by residualPlots, should be viewed as an internal function, and is included here to display its arguments, which can be used with residualPlots as well. The residualPlot function returns the curvature test as an invisible result.

residCurvTest computes the curvature test only. For any factors a boxplot will be drawn. For any polynomials, plots are against the linear term. Other non-standard predictors like B-splines are skipped.

Value

For lm objects, returns a data frame with one row for each plot drawn, one column for the curvature test statistic, and a second column for the corresponding p-value. This function is used primarily for its side effect of drawing residual plots.

Modified Functions for Summarizing Linear, Generalized Linear, and Some Other Models

Description

S

car package replacements for the summary (S) and confint (Confint) functions for lm, glm, multinom, and polr objects, with additional arguments but the same defaults as the original functions. The Confint method for "polr" objects profiles the likelihood to get confidence intervals for the regression parameters but uses Wald intervals for the thresholds. Default methods that call the standard R summary and confint functions are provided for the S and Confint generics, so the car functions should be safe to use in general. The default method for Confint also assumes that there is an appropriate coef method. For briefer model summaries, see brief.

Usage

```
S(object, brief, ...)
## S3 method for class 'lm'
S(object, brief=FALSE,
    correlation = FALSE, symbolic.cor = FALSE,
    vcov. = vcov(object, complete=FALSE), header = TRUE,
    resid.summary = FALSE, adj.r2 = FALSE,
    ...)
## S3 method for class 'glm'
S(object, brief=FALSE,
    exponentiate, dispersion, correlation = FALSE, symbolic.cor = FALSE,
    vcov. = vcov(object, complete=FALSE), header = TRUE,
    resid.summary = FALSE, ...)
## S3 method for class 'multinom'
S(object, brief=FALSE, exponentiate=FALSE, ...)
## S3 method for class 'polr'
S(object, brief=FALSE, exponentiate=FALSE, ...)
## S3 method for class 'lme'
S(object, brief=FALSE, correlation=FALSE, ...)
## S3 method for class 'lmerMod'
```

```
S(object, brief=FALSE, KR=FALSE, correlation=FALSE, ...)
## S3 method for class 'glmerMod'
S(object, brief=FALSE, correlation=FALSE, exponentiate, ...)
## S3 method for class 'data.frame'
S(object, brief=FALSE, ...)
## Default S3 method:
S(object, brief, ...)
## S3 method for class 'S.lm'
print(x, digits = max(3, getOption("digits") - 3),
  symbolic.cor = x$symbolic.cor, signif.stars = getOption("show.signif.stars"), ...)
## S3 method for class 'S.glm'
print(x, digits = max(3L, getOption("digits") - 3L),
  symbolic.cor = x$symbolic.cor, signif.stars = getOption("show.signif.stars"), ...)
## S3 method for class 'S.multinom'
print(x, digits = max(3, getOption("digits") - 3),
    signif.stars = getOption("show.signif.stars"), ...)
## S3 method for class 'S.polr'
print(x, digits = max(3, getOption("digits") - 3),
    signif.stars = getOption("show.signif.stars"), ...)
## S3 method for class 'S.lme'
print(x, digits=max(3, getOption("digits") - 3),
    signif.stars = getOption("show.signif.stars"), ...)
## S3 method for class 'S.lmerMod'
print(x, digits=max(3, getOption("digits") - 3),
    signif.stars = getOption("show.signif.stars"), ...)
## S3 method for class 'S.glmerMod'
print(x, digits=max(3, getOption("digits") - 3),
    signif.stars = getOption("show.signif.stars"), ...)
Confint(object, ...)
## S3 method for class 'lm'
Confint(object, estimate=TRUE,
    parm, level=0.95, vcov.=vcov(object, complete=FALSE), ...)
## S3 method for class 'glm'
Confint(object, estimate=TRUE, exponentiate=FALSE,
    vcov., dispersion, type=c("LR", "Wald"), ...)
```

Arguments

object a model or other object, e.g., of class "lm" as produced by a call to lm.

exponentiate for a "glm" or "glmerMod" model using the log or logit link, or a "polr"

or "multinom" model, show exponentiated coefficient estimates and confidence

bounds.

correlation, symbolic.cor

see summary.lm

x, digits, signif.stars

see summary.lm

dispersion see summary.glm

vcov. either a matrix giving the estimated covariance matrix of the estimates, or a

function that when called with object as an argument returns an estimated covariance matrix of the estimates. The default of vcov. = vcov uses the usual estimated covariance matrix. Other choices include the functions documented at hccm. See example below for using a bootstrap to estimate the covariance matrix. For the glm methods of Confint and S, if the vcov. or dispersion argument is specified, then Wald-based confidence limits are computed; otherwise the reported confidence limits are computed by profiling the likelihood. NOTE:

The dispersion and vcov. arguments may not *both* be specified.

header if TRUE, print the header for the summary output, default is TRUE

resid.summary if TRUE, print the five-number summary of the residuals in the summary, defaults

to FALSE

adj.r2 if TRUE, print the adjusted r-squared in the summary, default is FALSE

brief if TRUE, set header, resid. summary and adj.r. squared to FALSE, and sup-

press exponeniated coefficients for GLMs with log or logit link. For a data

frame, equivalent to use of brief.

KR if TRUE (default is FALSE), compute Kenward-Roger standard errors and Sat-

terthwaite degrees of freedom for t-tests. Warning: This computation can be

very time-consuming.

parm, level see confint

estimate show the estimated coefficients in the confidence-interval table; default is TRUE.

thresholds show confidence intervals for the estimated thresholds in the "polr" model.

type if "LR" (the default) compute confidence intervals based on the LR statistics by

profiling the likelihood; if "Wald" base confidence intervals on the Wald statistic

using the coefficient standard error and the normal distribution.

... additional arguments to be passed down, for consistency with summary and

confint methods

Details

All these functions mimic functions in the **stats** and other standard R packages for summarizing aspects of linear, generalized linear, and some other statistical models. The S function also provides an alterntive to summary for data frames, treating character variables as if they were factors.

The S and Confint functions add support for the vcov. argument for linear models, which allows specifying a covariance matrix for the regression coefficients other than the usual covariance matrix returned by the function vcov. This argument may be either the name of a function, so that the call to vcov. (object) returns a covariance matrix, or else vcov. is set equal to a covariance matrix. For example, setting vcov.=hccm uses 'proposal 3' described by Long and Ervin (2000) for a sandwich coefficient-variance estimator that may be robust against nonconstant variance (see hccm). Setting vcov. = hccm(object,type = "hc2") would use the matrix returned by the hccm function using proposal 2. For use with a bootstrap, see the examples below. The overall F-test in the S.lm output uses the supplied covariance matrix in a call to the linearHypothesis function.

The supplied print method for S.lm (and for other S methods) has additional arguments to customize the standard summary.lm output. Standard output is obtained by setting resid.summary=TRUE,adj.r2=TRUE.

Using a heterscedasticy-corrected covariance matrix computed using hccm with GLMs other than Gaussian is not justified; see the article by Freedman (2006).

The Summary.glm method for models fit with the log or logit link by default prints a table of exponentiated coefficients and their confidence limits; Summary.multinom and Summary.polr optionally print tables of exponentiated coefficients.

Value

The S.lm and S.glm functions return a list with all the elements shown at summary.lm and summary.glm. The S.multinom and S.polr functions return a list with all the elements shown at summary.multinom and summary.polr plus potentially a table of exponentiated coefficients and confidence bounds.

The Confint.lm function returns either the output from confint.lm if vcov. = vcov or Wald-type confidence intervals using the supplied covariance matrix for any other choice of vcov..

Finally, Confint applied to any object that does not inherit from "lm", "multinom", or "polr" simply calls confint, along with, by default, using coef to add a column of estimates to the confidence limits.

## End(Not run)
```

scatter3d

Three-Dimensional Scatterplots and Point Identification

Description

The scatter3d function uses the rgl package to draw 3D scatterplots with various regression surfaces. The function Identify3d allows you to label points interactively with the mouse: Press the right mouse button (on a two-button mouse) or the centre button (on a three-button mouse), drag a rectangle around the points to be identified, and release the button. Repeat this procedure for each point or set of "nearby" points to be identified. To exit from point-identification mode, click the right (or centre) button in an empty region of the plot.

Usage

```
scatter3d(x, ...)
## S3 method for class 'formula'
scatter3d(formula, data, subset, radius, xlab, ylab, zlab, id=FALSE, ...)
## Default S3 method:
scatter3d(x, y, z,
  xlab=deparse(substitute(x)), ylab=deparse(substitute(y)),
  zlab=deparse(substitute(z)), axis.scales=TRUE, axis.ticks=FALSE,
  revolutions=0,
 bg.col=c("white", "black"),
  axis.col=if (bg.col == "white") c("darkmagenta", "black", "darkcyan")
            else c("darkmagenta", "white", "darkcyan"),
  surface.col=carPalette()[-1], surface.alpha=0.5,
 neg.res.col="magenta", pos.res.col="cyan",
  square.col=if (bg.col == "white") "black" else "gray",
  point.col="yellow", text.col=axis.col,
  grid.col=if (bg.col == "white") "black" else "gray",
  fogtype=c("exp2", "linear", "exp", "none"),
  residuals=(length(fit) == 1),
  surface=TRUE, fill=TRUE,
  grid=TRUE, grid.lines=26, df.smooth=NULL, df.additive=NULL,
  sphere.size=1, radius=1, threshold=0.01, speed=1, fov=60,
  fit="linear", groups=NULL, parallel=TRUE,
  ellipsoid=FALSE, level=0.5, ellipsoid.alpha=0.1, id=FALSE,
 model.summary=FALSE, ...)
Identify3d(x, y, z, axis.scales=TRUE, groups = NULL, labels = 1:length(x),
col = c("blue", "green", "orange", "magenta", "cyan", "red", "yellow", "gray"),
offset = ((100/length(x))^{(1/3)}) * 0.02)
```

Arguments

formula "model" formula, of the form $y \sim x + z$ or to plot by groups $y \sim x + z \mid g$, where

g evaluates to a factor or other variable dividing the data into groups.

data data frame within which to evaluate the formula.
subset expression defining a subset of observations.

x variable for horizontal axis.

y variable for vertical axis (response).
z variable for out-of-screen axis.

xlab, ylab, zlab

axis labels.

axis.scales if TRUE, label the values of the ends of the axes. *Note*: For Identify3d to work

properly, the value of this argument must be the same as in scatter3d.

axis.ticks if TRUE, print interior axis-"tick" labels; the default is FALSE. (The code for this

option was provided by David Winsemius.)

revolutions number of full revolutions of the display.

bg.col background colour; one of "white", "black".

axis.col colours for axes; if axis.scales is FALSE, then the second colour is used for all

three axes.

surface.col vector of colours for regression planes, used in the order specified by fit; for

multi-group plots, the colours are used for the regression surfaces and points in

the several groups.

surface.alpha transparency of regression surfaces, from 0.0 (fully transparent) to 1.0 (opaque);

default is 0.5.

neg.res.col, pos.res.col

colours for lines representing negative and positive residuals.

square.col colour to use to plot squared residuals.

point.col colour of points.

text.col colour of axis labels.

grid.col colour of grid lines on the regression surface(s).

fogtype type of fog effect; one of "exp2", "linear", "exp", "none".

residuals plot residuals if TRUE; if residuals="squares", then the squared residuals are

shown as squares (using code adapted from Richard Heiberger). Residuals are

available only when there is one surface plotted.

surface plot surface(s) (TRUE or FALSE).

fill fill the plotted surface(s) with colour (TRUE or FALSE).
grid plot grid lines on the regression surface(s) (TRUE or FALSE).

grid.lines number of lines (default, 26) forming the grid, in each of the x and z directions.

df. smooth degrees of freedom for the two-dimensional smooth regression surface; if NULL

(the default), the gam function will select the degrees of freedom for a smoothing spline by generalized cross-validation; if a positive number, a fixed regression

spline will be fit with the specified degrees of freedom.

df.additive degrees of freedom for each explanatory variable in an additive regression; if NULL (the default), the gam function will select degrees of freedom for the smoothing splines by generalized cross-validation; if a positive number or a vector of two positive numbers, fixed regression splines will be fit with the specified degrees of freedom for each term. sphere.size general size of spheres representing points; the actual size is dependent on the number of observations. radius relative radii of the spheres representing the points. This is normally a vector of the same length as the variables giving the coordinates of the points, and for the formula method, that must be the case or the argument may be omitted, in which case spheres are the same size; for the default method, the default for the argument, 1, produces spheres all of the same size. The radii are scaled so that their median is 1. threshold if the actual size of the spheres is less than the threshold, points are plotted instead. relative speed of revolution of the plot. speed fov field of view (in degrees); controls degree of perspective. one or more of "linear", "quadratic", "smooth", "additive"; to display fit fitted surface(s); partial matching is supported – e.g., c("lin", "quad"). groups if NULL (the default), no groups are defined; if a factor, a different surface or set of surfaces is plotted for each level of the factor; in this event, the colours in surface.col are used successively for the points, surfaces, and residuals corresponding to each level of the factor. parallel when plotting surfaces by groups, should the surfaces be constrained to be parallel? A logical value, with default TRUE. ellipsoid plot concentration ellipsoid(s) (TRUE or FALSE). level expected proportion of bivariate-normal observations included in the concentration ellipsoid(s); default is 0.5. ellipsoid.alpha transparency of ellipsoids, from 0.0 (fully transparent) to 1.0 (opaque); default id FALSE, TRUE, or a list controlling point identification, similar to showLabels for 2D plots (see Details). model.summary print summary or summaries of the model(s) fit (TRUE or FALSE). scatter3d rescales the three variables internally to fit in the unit cube; this rescaling will affect regression coefficients. labels text labels for the points, one for each point; defaults to the observation indices. col colours for the point labels, given by group. There must be at least as many colours as groups; if there are no groups, the first colour is used. Normally, the colours would correspond to the surface.col argument to scatter3d.

vertical displacement for point labels (to avoid overplotting the points).

arguments to be passed down.

offset

Details

The id argument to scatter3d can be FALSE, TRUE (in which case 2 points will be identified according to their Mahalanobis distances from the center of the data), or a list containing any or all of the following elements:

method if "mahal" (the default), relatively extreme points are identified automatically according to their Mahalanobis distances from the centroid (point of means); if "identify", points are identified interactively by right-clicking and dragging a box around them; right-click in an empty area to exit from interactive-point-identification mode; if "xz", identify extreme points in the predictor plane; if "y", identify unusual values of the response; if "xyz" identify unusual values of an variable; if "none", no point identification. See showLabels for more information.

n Number of relatively extreme points to identify automatically (default, 2, unless method="identify", in which case identification continues until the user exits).

labels text labels for the points, one for each point; in the default method defaults to the observation indices, in the formula method to the row names of the data.

offset vertical displacement for point labels (to avoid overplotting the points).

Value

scatter3d does not return a useful value; it is used for its side-effect of creating a 3D scatterplot. Identify3d returns the labels of the identified points.

Note

You have to install the rgl package to produce 3D plots. On a Macintosh (but not on Windows or Linux), you may also need to install the X11 windowing system. Go to https://www.xquartz.org/ and click on the link for XQuartz. Double-click on the downloaded disk-image file, and then double-click on XQuartz.pkg to start the installer. You may take all of the defaults in the installation. After XQuartz is installed, you should restart your Macintosh.

scatterplot

Enhanced Scatterplots with Marginal Boxplots, Point Marking, Smoothers, and More

Description

This function uses basic R graphics to draw a two-dimensional scatterplot, with options to allow for plot enhancements that are often helpful with regression problems. Enhancements include adding marginal boxplots, estimated mean and variance functions using either parametric or nonparametric methods, point identification, jittering, setting characteristics of points and lines like color, size and symbol, marking points and fitting lines conditional on a grouping variable, and other enhancements. sp is an abbreviation for scatterplot.

Usage

Arguments

vector of horizontal coordinates (or first argument of generic function). Х

vector of vertical coordinates. У

formula a model formula, of the form $y \sim x$ or, if plotting by groups, $y \sim x \mid z$, where

z evaluates to a factor or other variable dividing the data into groups. If x is a

factor, then parallel boxplots are produced using the Boxplot function.

data data frame within which to evaluate the formula.

subset expression defining a subset of observations.

boxplots if "x" a marginal boxplot for the horizontal x-axis is drawn below the plot; if

> "y" a marginal boxplot for vertical y-axis is drawn to the left of the plot; if "xy" both marginal boxplots are drawn; set to "" or FALSE to suppress both boxplots.

controls adding a fitted regression line to the plot. if regLine=FALSE, no line regLine

is drawn. If TRUE, the default, an OLS line is fit. This argument can also be a list. The default of TRUE is equivalent to regLine=list(method=lm, lty=1, lwd=2, col=col),

which specifies using the 1m function to estimate the fitted line, to draw a solid line (lty=1) of width 2 times the nominal width (lwd=2) in the color given by

the first element of the col argument described below.

legend when the plot is drawn by groups and legend=TRUE, controls placement and

properties of a legend; if FALSE, the legend is suppressed. Can be a list of named arguments, as follows: title for the legend; inset, giving space as a proportion of the axes to offset the legend from the axes; coords specifying the position of the legend in any form acceptable to the legend function or, if not given, the legend is placed above the plot in the upper margin; columns for the legend, determined automatically to prefer a horizontal layout if not given explicitly; cex giving the relative size of the legend symbols and text. TRUE (the default) is equiv-

alent to list(title=deparse(substitute(groups)),inset=0.02,cex=1).

controls point identification; if FALSE (the default), no points are identified; can be a list of named arguments to the showLabels function; TRUE is equivalent to list(method="mahal", n=2, cex=1, col=carPalette()[-1], location="lr"), which identifies the 2 points (in each group) with the largest Mahalanobis distances from the center of the data. See showLabels for a description of the other arguments. The default behavior of id is not the same in all graphics functions

in car, as the method used depends on the type of plot.

ellipse controls plotting data-concentration ellipses. If FALSE (the default), no ellipses

> are plotted. Can be a list of named values giving levels, a vector of one or more bivariate-normal probability-contour levels at which to plot the ellipses; robust, a logical value determing whether to use the cov. trob function in the MASS package to calculate the center and covariance matrix for the data ellipses; and fill and fill. alpha, which control whether the ellipse is filled and the trans-

parency of the fill. TRUE is equivalent to list(levels=c(.5,.95), robust=TRUE, fill=TRUE, fill.alp

grid If TRUE, the default, a light-gray background grid is put on the graph

specifies a nonparametric estimate of the mean or median function of the vertical axis variable given the horizontal axis variable and optionally a nonparametric estimate of the conditional variance. If smooth=FALSE neither function is drawn.

If smooth=TRUE, then both the mean function and variance funtions are drawn

id

smooth

for ungrouped data, and the mean function only is drawn for grouped data. The default smoother is loessLine, which uses the loess function from the **stats** package. This smoother is fast and reliable. See the details below for changing the smoother, line type, width and color, of the added lines, and adding arguments for the smoother.

groups a factor or other variable dividing the data into groups; groups are plotted with

different colors, plotting characters, fits, and smooths. Using this argument is

equivalent to specifying the grouping variable in the formula.

by groups if TRUE (the default when there are groups), regression lines are fit by groups.

xlab label for horizontal axis. ylab label for vertical axis.

log same as the log argument to plot, to produce log axes.

jitter a list with elements x or y or both, specifying jitter factors for the horizontal and

vertical coordinates of the points in the scatterplot. The jitter function is used to randomly perturb the points; specifying a factor of 1 produces the default

jitter. Fitted lines are unaffected by the jitter.

col with no grouping, this specifies a color for plotted points; with grouping, this

argument should be a vector of colors of length at least equal to the number of

groups. The default is value returned by carPalette[-1].

pch plotting characters for points; default is the plotting characters in order (see par).

cex sets the size of plotting characters, with cex=1 the standard size. You can also set

the sizes of other elements with the arguments cex.axis, cex.lab, cex.main,

and cex. sub. See par.

reset.par if TRUE (the default) then plotting parameters are reset to their previous values

when scatterplot exits; if FALSE then the mar and mfcol parameters are altered for the current plotting device. Set to FALSE if you want to add graphical

elements (such as lines) to the plot.

... other arguments passed down and to plot. For example, the argument las sets

the style of the axis labels, and xlim and ylim set the limits on the horizontal

and vertical axes, respectively; see par.

Details

Many arguments to scatterplot were changed in version 3 of **car** to simplify use of this function.

The smooth argument is used to control adding smooth curves to the plot to estimate the conditional center of the vertical axis variable given the horizontal axis variable, and also the conditional variability. Setting smooth=FALSE omits all smoothers, while smooth=TRUE, the default, includes default smoothers. Alternatively smooth can be set to a list of subarguments that provide finer control over the smoothing.

The default behavior of smooth=TRUE is equivalent to smooth=list(smoother=loessLine,var=!by.groups,lty.var=2,l specifying the default loessLine smoother for the conditional mean smooth and variance smooth. The color of the smooths is the same of the color of the points, but this can be changed with the arguments col.smooth and col.var.

Additional available smoothers are gamLine which uses the gam function and quantregLine which uses quantile regression to estimate the median and quartile functions using rqss. All of these

smoothers have one or more arguments described on their help pages, and these arguments can be added to the smooth argument; for example, smooth = list(span=1/2) would use the default loessLine smoother, include the variance smooth, and change the value of the smoothing parameter to 1/2.

For loessLine and gamLine the variance smooth is estimated by separately smoothing the squared positive and negative residuals from the mean smooth, using the same type of smoother. The displayed curves are equal to the mean smooth plus the square root of the fit to the positive squared residuals, and the mean fit minus the square root of the smooth of the negative squared residuals. The lines therefore represent the comnditional variability at each value on the horizontal axis. Because smoothing is done separately for positive and negative residuals, the variation shown will generally not be symmetric about the fitted mean function. For the quantregLine method, the center estimates the conditional median, and the variability estimates the lower and upper quartiles of the estimated conditional distribution.

The default depection of the variance functions is via a shaded envelope between the upper and lower estimate of variability. setting the subarguement style="lines" will display only the boundaries of this region, and style="none" suppresses variance smoothing.

For style="filled" several subarguments modify the appearance of the region: codealpha is a number between 0 and 1 that specifies opacity with defualt 0.15, border, TRUE or FALSE specifies a border for the envelope, and vertical either TRUE or FALSE, modifies the behavior of the envelope at the edges of the graph.

The sub-arguments spread, lty.spread and col.spread of the smooth argument are equivalent to the newer var, col.var and lty.var, respectively, recognizing that the spread is a measure of conditional variability.

Value

If points are identified, their labels are returned; otherwise NULL is returned invisibly.

scatterplotMatrix

Scatterplot Matrices

Description

This function provides a convenient interface to the pairs function to produce enhanced scatterplot matrices, including univariate displays on the diagonal and a variety of fitted lines, smoothers, variance functions, and concentration ellipsoids. spm is an abbreviation for scatterplotMatrix.

Usage

```
## S3 method for class 'formula'
scatterplotMatrix(formula, data=NULL, subset, ...)

## Default S3 method:
scatterplotMatrix(x, smooth = TRUE,
    id = FALSE, legend = TRUE, regLine = TRUE,
    ellipse = FALSE, var.labels = colnames(x), diagonal = TRUE,
    plot.points = TRUE, groups = NULL, by.groups = TRUE,
    use = c("complete.obs", "pairwise.complete.obs"), col =
    carPalette()[-1], pch = 1:n.groups, cex = par("cex"),
    cex.axis = par("cex.axis"), cex.labels = NULL,
    cex.main = par("cex.main"), row1attop = TRUE, ...)
```

spm(x, ...)

Arguments

Χ

a data matrix or a numeric data frame.

formula

a one-sided "model" formula, of the form $\sim x1 + x2 + \ldots + xk$ or $\sim x1 + x2 + \ldots + xk$ | z where z evaluates to a factor or other variable to divide the data into groups.

data

for scatterplotMatrix.formula, a data frame within which to evaluate the formula.

subset

expression defining a subset of observations.

smooth

specifies a nonparametric estimate of the mean or median function of the vertical axis variable given the horizontal axis variable and optionally a nonparametric estimate of the spread or variance function. If smooth=FALSE neither function is drawn. If smooth=TRUE, then both the mean function and variance funtions are drawn for ungrouped data, and the mean function only is drawn for grouped data. The default smoother is loessLine, which uses the loess function from the stats package. This smoother is fast and reliable. See the details below for changing the smoother, line type, width and color, of the added lines, and adding arguments for the smoother.

id

controls point identification; if FALSE (the default), no points are identified; can be a list of named arguments to the showLabels function; TRUE is equivalent to list(method="mahal",n=2,cex=1,location="lr"), which identifies the 2 points (in each group, if by.groups=TRUE) with the largest Mahalanobis distances from the center of the data; list(method="identify") for interactive point identification is not allowed.

legend

controls placement of a legend if the plot is drawn by groups; if FALSE, the legend is suppressed. Can be a list with the named elementcoords specifying the position of the legend in any form acceptable to the legend function; TRUE (the default) is equivalent to list(coords=NULL), for which placement will vary by the the value of the diagonal argument—e.g., "topright" for diagonal=TRUE.

regLine

controls adding a fitted regression line to each plot, or to each group of points if by.groups=TRUE. If regLine=FALSE, no line is drawn. This argument can also be a list with named list, with default regLine=TRUE equivalent to regLine = list(method=lm,lty=1,lwd=2,col=col[1]) specifying the name of the function that computes the line, with line type 1 (solid) of relative line width 2 and the color equal to the first value in the argument col. Setting method=MASS::rlm would fit using a robust regression.

ellipse

controls plotting data-concentration ellipses. If FALSE (the default), no ellipses are plotted. Can be a list of named values giving levels, a vector of one or more bivariate-normal probability-contour levels at which to plot the ellipses; robust, a logical value determing whether to use the cov.trob function in the MASS package to calculate the center and covariance matrix for the data ellipses; and fill and fill.alpha, which control whether the ellipse is filled and the trans-

parency of the fill. TRUE is equivalent to list(levels=c(.5,.95), robust=TRUE, fill=TRUE, fill.alp

var.labels variable labels (for the diagonal of the plot).

diagonal contents of the diagonal panels of the plot. If diagonal=TRUE adaptive kernel

density estimates are plotted, separately for each group if grouping is present. diagonal=FALSE suppresses the diagonal entries. See details below for other

choices for the diagonal.

plot.points if TRUE the points are plotted in each off-diagonal panel.

groups a factor or other variable dividing the data into groups; groups are plotted with

different colors and plotting characters.

by groups if TRUE, the default, regression lines and smooths are fit by groups.

use if "complete.obs" (the default), cases with missing data are omitted; if "pairwise.complete.obs"), all

valid cases are used in each panel of the plot.

pch plotting characters for points; default is the plotting characters in order (see par).

col colors for points; the default is carPalette starting at the second color. The

color of the regLine and smooth are the same as for points but can be changed

using the the regLine and smooth arguments.

cex relative size of plotted points
cex.axis relative size of axis labels

cex.labels relative size of labels on the diagonal cex.main relative size of the main title, if any

row1attop If TRUE (the default) the first row is at the top, as in a matrix, as opposed to at

the bottom, as in graph (argument suggested by Richard Heiberger).

... arguments to pass down.

Details

Many arguments to scatterplotMatrix were changed in version 3 of **car**, to simplify use of this function.

The smooth argument is usually either set to TRUE or FALSE to draw, or omit, the smoother. Alternatively smooth can be set to a list of arguments. The default behavior of smooth=TRUE is equivalent to smooth=list(smoother=loessLine,spread=TRUE,lty.smooth=1,lwd.smooth=1.5,lty.spread=3,lwd.spread=1), specifying the smoother to be used, including the spread or variance smooth, and the line widths and types for the curves. You can also specify the colors you want to use for the mean and variance smooths with the arguments col.smooth and col.spread. Alternative smoothers are gamline which uses the gam function from the **mgcv** package, and quantregLine which uses quantile regression to estimate the median and quartile functions using rqss from the quantreg package. All of these smoothers have one or more arguments described on their help pages, and these arguments can be added to the smooth argument; for example, smooth = list(span=1/2) would use the default loessLine smoother, include the variance smooth, and change the value of the smoothing parameter to 1/2. For loessLine and gamLine the variance smooth is estimated by separately smoothing the squared positive and negative residuals from the mean smooth, using the same type of smoother. The displayed curves are equal to the mean smooth plus the square root of the fit to the positive squared residuals, and the mean fit minus the square root of the smooth of the negative squared residuals. The lines therefore represent the commditional variability at each value on the horizontal axis. Because smoothing is done separately for positive and negative residuals, the variation shown will generally not be symmetric about the fitted mean function. For the quantregLine

method, the center estimates the median for each value on the horizontal axis, and the spread estimates the lower and upper quartiles of the estimated conditional distribution for each value of the horizontal axis.

The sub-arguments spread, lty.spread and col.spread of the smooth argument are equivalent to the newer var, col.var and lty.var, respectively, recognizing that the spread is a measure of conditional variability.

By default the diagonal argument is used to draw kernel density estimates of the variables by setting diagonal=TRUE, which is equivalent to setting diagonal = list(method="adaptiveDensity", bw=bw.nrd0, adjust=1, kernel additional arguments shown are descibed at adaptiveKernel. The other methods avaliable, with their default arguments, are diagonal=list(method="density", bw="nrd0", adjust=1, kernel="gaussian", na.rm which uses density for nonadaptive kernel density estimation; diagonal=list(method="histogram", breaks="FD") which uses hist for drawing a histogram that ignores grouping, if present; diagonal=list(method="boxplot") with no additional arguments which draws (parallel) boxplots; diagonal=list(method="qqplot") with no additional arguments which draws a normal QQ plot; and diagonal=list(method="oned") with no additional arguments which draws a rug plot tilted to the diagonal, as suggested by Richard Heiberger.

Earlier versions of scatterplotMatrix included arguments transform and family to estimate power transformations using the powerTransform function before drawing the plot. The same functionality can be achieved by calling powerTransform directly to estimate a transformation, saving the transformed variables, and then plotting.

Value

NULL, returned invisibly. This function is used for its side effect: producing a plot. If point identification is used, a vector of identified points is returned.

ScatterplotSmoothers 125

Description

These smoothers are used to draw nonparametric-regression lines on scatterplots produced by the scatterplot, scatterplotMatrix, and several other car functions. The functions are not meant to be called directly by the user, although the user can supply options via the smoother args argument, the contents of which vary by the smoother (see *Details* below). The gamLine smoother uses the gam function in the **mgcv** package, the loessLine smoother uses the loess function in the **stats** package, and the quantregLine smoother uses the rqss function in the **quantreg** package.

Usage

Arguments

x	horizontal coordinates of points.
У	vertical coordinates of points.
col	line color.
log.x	should be set to TRUE (default is FALSE) if the horizontal axis is logged.
log.y	should be set to TRUE (default is FALSE) if the vertical axis is logged.
spread, var	the default is to plot only an estimated mean or median function. If either of these arguments is TRUE, then a measure of variability is also plotted.
smoother.args	additional options accepted by the smoother, in the form of a list of named values (see <i>Details</i> below).
draw	if TRUE, the default, draw the smoother on the currently active graph. If FALSE, return a list with coordinates x and y for the points that make up the smooth and if requested $x.pos,y.pos,x.neg,y.neg$ for the spread smooths.
offset	For use when spread=TRUE, the vertical axis is $sqrt(offset^2 + variance smooth)$.

Details

The loessLine function is a re-implementation of the loess smoother that was used in **car** prior to September 2012. The main enhancement is the ability to set more options through the smoother args argument.

126 ScatterplotSmoothers

The gamLine function is more general than loessLine because it supports fitting a generalized spline regression model, with user-specified error distribution and link function.

The quantregLine function fits a model using splines with estimation based on L1 regression for the median and quantile regression the (optional) spread. It is likely to be more robust than the other smoothers.

The smoother.args argument is a list of named elements (or sub-arguments) used to pass additional arguments to the smoother. As of November, 2016, the smoother is evaluated by default at an equally spaced grid of 50 points in the range of the horizontal variable. With any of the smoothers, you can change to, say, 100 evaluation points via the argument smoother.args=list(evaluation=100). As of version 3.0-1, the smoother.args elements col.var, lty.var, and lwd.var are equivalent to col.spread, lty.spread, and lwd.spread, respectively. The style sub-argument controls how spread/variance envelopes are displayed, with choices "filled" (the default), "lines", and "none" (which is equivalent to var=FALSE). The alpha subargument controls the transparency/opacity of filled spread envelopes with allowable values between 0 and 1 (default 0.15). The border subargument controls whether a border line is drawn around the filled region (the default is TRUE). The vertical subargument controls whether the left and right ends of the filled region are forced to be vertical (the default is TRUE).

For loessLine, the default is smoother.args=list(lty.smooth=1,lwd.smooth=2,lty.spread=4,lwd.spread=2,style (Prior to November 2016, the default span was 1/2.) The elements lty.smooth, lwd.smooth, and col.spread are the line type, line width, and line color, respectively of the mean or median smooth; lty.spread, lwd.spread, and col.spread are the line type, width, and color of the spread smooths, if requested. The elements span, degree, and family are passed as arguments to the loess function, along with iterations robustness iterations.

For gamLine, the default is smoother.args=list(lty.smooth=1,lwd.smooth=2,lty.spread=4,lwd.spread=2,style='
The first six elements are as for loessLine. The next two elements are passed to the gam function to
control smoothing: k=-1 allows gam to choose the number of splines in the basis function; bs="tp"
provides the type of spline basis to be used, with "tp" for the default thin-plate splines. The last
three arguments specify a distributional family, link function, and weights as in generalized linear
models. See the examples below. The spread element is ignored unless family="gaussian" and
link=NULL.

For quantregLine, the default is smoother.args=list(lty.smooth=1,lwd.smooth=2,lty.spread=4,lwd.spread=2,st The first six elements are as for loessLine. The last element is passed to the qss function in quantreg. It is a smoothing parameter, by default a robust estimate of the scale of the horizontal axis variable. This is an arbitrary choice, and may not work well in all circumstances.

```

showLabels

Functions to Identify and Mark Extreme Points in a 2D Plot.

Description

This function is called by several graphical functions in the **car** package to mark extreme points in a 2D plot. Although the user is unlikely to call this function directly, the documentation below applies to all these other functions.

Usage

```
showLabels(x, y, labels=NULL, method="identify",
  n = length(x), cex=1, col=carPalette()[1], location=c("lr", "ab", "avoid"), ...)
```

128 showLabels

Arguments

x Plotted horizontal coordinates.

y Plotted vertical coordinates.

labels Plotting labels. When called from within a **car** plotting function, the labels are

automatically obtained from the row names in the data frame used to create the modeling object. If labels=NULL, case numbers will be used. If labels are long, the substr or abbreviate functions can be used to shorten them. Users may supply their own labels as a character vector of length equal to the number of plotted points. For use with **car** plotting functions, the number of plotted points is equal to the number of rows of data that have neither missing values nor are excluded using the 'subset' argument. When called directly, the length of labels

shoud equal the length of x.

method How points are to be identified. See Details below.

n Number of points to be identified. If set to 0, no points are identified.

cex Controls the size of the plotted labels. The default is 1.

col Controls the color of the plotted labels. The default is the first element returned

by carPalette().

location Where should the label be drawn? The default is "lr" to draw the label to the

left of the point for points in the right-half of the graph and to the right for points in the left-half. The other option is "ab" for above the point for points below the middle of the graph and above the point below the middle. Finally, "avoid"

tries to avoid over-plotting labels.

... not used.

Details

The argument method determine how the points to be identified are selected. For the default value of method="identify", the identify function is used to identify points interactively using the mouse. Up to n points can be identified, so if n=0, which is the default in many functions in the **car** package, then no point identification is done.

Automatic point identification can be done depending on the value of the argument method.

- method = "x" select points according to their value of abs(x -mean(x))
- method = "y" select points according to their value of abs(y -mean(y))
- method = "r" select points according to their value of abs(y), as may be appropriate in residual plots, or others with a meaningful origin at 0
- method = "mahal" Treat (x,y) as if it were a bivariate sample, and select cases according to their Mahalanobis distance from (mean(x), mean(y))
- method can be a vector of the same length as x consisting of values to determine the points to
 be labeled. For example, for a linear model m, setting method=cooks.distance(m) will label
 the points corresponding to the largest values of Cook's distance, or method = which(abs(residuals(m, type="pears"))
 > 2 would label all observations with Pearson residuals greater than 2 in absolute value. Warning: If missing data are present, points may be incorrectly labelled.

sigmaHat 129

• method can be a vector of case numbers or case-labels, in which case those cases will be labeled. Warning: If missing data are present, a list of case numbers may identify the wrong points. A list of case labels, however, will work correctly with missing values.

• method = "none" causes no point labels to be shown.

With showLabels, the method argument can be a list, so, for example method=list("x","y") would label according to the horizontal and vertical axes variables.

Finally, if the axes in the graph are logged, the function uses logged-variables where appropriate.

Value

A function primarily used for its side-effect of drawing point labels on a plot. Returns invisibly the labels of the selected points, or NULL if no points are selected. Although intended for use with other functions in the **car** package, this function can be used directly.

Examples

sigmaHat

Return the scale estimate for a regression model

Description

This function provides a consistent method to return the estimated scale from a linear, generalized linear, nonlinear, or other model.

Usage

```
sigmaHat(object)
```

130 some

Arguments

object

A regression object of type lm, glm or nls

Details

For an lm or nls object, the returned quantity is the square root of the estimate of σ^2 . For a glm object, the returned quantity is the square root of the estimated dispersion parameter.

Value

A nonnegative number

Author(s)

Sanford Weisberg, <sandy@umn.edu>

Examples

```
m1 <- lm(prestige \sim income + education, data=Duncan) sigmaHat(m1)
```

some

Sample a Few Elements of an Object

Description

Randomly select a few elements of an object, typically a data frame, matrix, vector, or list. If the object is a data frame or a matrix, then rows are sampled.

Usage

```
some(x, ...)
## S3 method for class 'data.frame'
some(x, n=10, cols=NULL, ...)
## S3 method for class 'matrix'
some(x, n=10, cols=NULL, ...)
## Default S3 method:
some(x, n=10, ...)
```

Arguments

```
    the object to be sampled.
    n number of elements to sample.
    if NULL, use all columns, if a vector of column names or numbers, use only the columns indicated
    arguments passed down.
```

spreadLevelPlot 131

Value

Sampled elements or rows.

Note

These functions are adapted from head and tail in the utils package.

spreadLevelPlot

Spread-Level Plots

Description

Creates plots for examining the possible dependence of spread on level, or an extension of these plots to the studentized residuals from linear models.

Usage

```
spreadLevelPlot(x, ...)
slp(...)

## S3 method for class 'formula'
spreadLevelPlot(x, data=NULL, subset, na.action,
    main=paste("Spread-Level Plot for", varnames[response],
    "by", varnames[-response]), ...)

## Default S3 method:
spreadLevelPlot(x, by, robust.line=TRUE,
start=0, xlab="Median", ylab="Hinge-Spread",
point.labels=TRUE, las=par("las"),
main=paste("Spread-Level Plot for", deparse(substitute(x)),
```

132 spreadLevelPlot

Arguments

x a formula of the form $y \sim x$, where y is a numeric vector and x is a factor, or an

Im object to be plotted; alternatively a numeric vector.

data an optional data frame containing the variables to be plotted. By default the vari-

ables are taken from the environment from which spreadLevelPlot is called.

subset an optional vector specifying a subset of observations to be used.

na.action a function that indicates what should happen when the data contain NAs. The

default is set by the na. action setting of options.

by a factor, numeric vector, or character vector defining groups.

robust.line if TRUE a robust line is fit using the rlm function in the MASS package; if FALSE

a line is fit using 1m.

start add the constant start to each data value.

main title for the plot.

xlab label for horizontal axis.
ylab label for vertical axis.

point.labels if TRUE label the points in the plot with group names.

las if 0, ticks labels are drawn parallel to the axis; set to 1 for horizontal labels (see

par).

col color for points; the default is the first entry in the current **car** palette (see

carPalette and par).

col.lines for the default method, the line color, defaulting to the second entry in the car

color palette; for the "1m" method, a vector of two colors for, respectively, the fitted straight line and a nonparametric regression smooth line, default to the

second and third entries in the car color palette.

pch plotting character for points; default is 1 (a circle, see par).

lwd line width; default is 2 (see par).

grid If TRUE, the default, a light-gray background grid is put on the graph

spreadLevelPlot 133

id controls point identification; if FALSE (the default), no points are identified; can

be a list of named arguments to the ${\tt showLabels}$ function; TRUE is equivalent to

list(method=list("x","y"),n=2,cex=1,col=carPalette()[1],location="lr"),

which identifies the 2 points the most extreme horizontal ("X", absolute studentized residual) values and the 2 points with the most extreme horizontal ("Y",

fitted values) values.

smooth specifies the smoother to be used along with its arguments; if FALSE, no smoother

is shown; can be a list giving the smoother function and its named arguments;

TRUE, the default, is equivalent to list(smoother=loessLine). See ScatterplotSmoothers

for the smoothers supplied by the **car** package and their arguments.

... arguments passed to plotting functions.

Details

Except for linear models, computes the statistics for, and plots, a Tukey spread-level plot of log(hinge-spread) vs. log(median) for the groups; fits a line to the plot; and calculates a spread-stabilizing transformation from the slope of the line.

For linear models, plots log(abs(studentized residuals) vs. log(fitted values). Point labeling was added in November, 2016.

The function slp is an abbreviation for spreadLevelPlot.

Value

An object of class spreadLevelPlot containing:

Statistics a matrix with the lower-hinge, median, upper-hinge, and hinge-spread for each

group. (Not for an 1m object.)

PowerTransformation

spread-stabilizing power transformation, calculated as 1 - slope of the line fit

to the plot.

strings2factors

Convert Character-String Variables in a Data Frame to Factors

Description

Converts the character variables (or a subset of these variables) in a data frame to factors, with optional control of the order of the resulting factor levels.

Usage

Arguments

object a data frame or an object inheriting from the "data. frame" class.

which an optional character vector of names or column numbers of the character vari-

ables to be converted to factors; if absent, *all* character variables will be converted, except as excluded by the not and exclude.unique arguments (see be-

low).

not an optional character vector of names or column numbers of character variables

not to be converted to factors.

exclude.unique if TRUE (the default), character variables all of whose values are unique (i.e., all

different from each other) are not converted to factors. Such variables, which would have as many levels as there are cases, are typically case identifiers and not categorical variables. If FALSE, character variables all of whose values are

unique are converted to factors with a warning.

levels an optional named list, each element of which is a character vector of levels

of the corresponding factor. This argument allows you to control the order of levels of the factor; if omitted, or if a particular factor is omitted from the list,

the levels will be in the default alphabetic order.

verbose if TRUE (the default), the names of the character variables that were converted to

factors are printed on the console.

... not used.

Value

a data frame with (some) character variables replaced by corresponding factors.

subsets

Plot Output from regsubsets Function in leaps package

Description

The regsubsets function in the **leaps** package finds optimal subsets of predictors based on some criterion statistic. This function plots a measure of fit against subset size.

Usage

```
subsets(object, ...)
## S3 method for class 'regsubsets'
subsets(object,
    names=abbreviate(object$xnames, minlength = abbrev),
    abbrev=1, min.size=1, max.size=length(names),
    legend="interactive",
    statistic=c("bic", "cp", "adjr2", "rsq", "rss"),
    las=par('las'), cex.subsets=1, ...)
```

Arguments

object	a regsubsets object produced by the regsubsets function in the leaps package.
names	a vector of (short) names for the predictors, excluding the regression intercept, if one is present; if missing, these are derived from the predictor names in object.
abbrev	minimum number of characters to use in abbreviating predictor names.

136 subsets

minimum size subset to plot; default is 1. min.size max.size maximum size subset to plot; default is number of predictors. legend If not FALSE, in which case the legend is suppressed, the coordinates at which to place a legend of the abbreviated predictor names on the plot, in a form recognized by the legend function. If "interactive", the legend is placed on the plot interactively with the mouse. By expanding the left or right plot margin, you can place the legend in the margin, if you wish (see par). statistic to plot for each predictor subset; one of: "bic", Bayes Information statistic Criterion; "cp", Mallows's C_p ; "adjr2", R^2 adjusted for degrees of freedom; "rsq", unadjusted R^2 ; "rss", residual sum of squares. if 0, ticks labels are drawn parallel to the axis; set to 1 for horizontal labels (see las par). cex.subsets can be used to change the relative size of the characters used to plot the regression subsets; default is 1. arguments to be passed down to subsets.regsubsets and plot.

Value

NULL if the legend is TRUE; otherwise a data frame with the legend.

regsubsets

Examples

symbox 137

symbox

Boxplots for transformations to symmetry

Description

symbox first transforms x to each of a series of selected powers, with each transformation standardized to mean 0 and standard deviation 1. The results are then displayed side-by-side in boxplots, permiting a visual assessment of which power makes the distribution reasonably symmetric. For the "lm" method, the response variable in the model is successively transformed.

Usage

Arguments

a numeric vector. Х formula a one-sided formula specifying a single numeric variable. data, subset, na.action as for statistical modeling functions (see, e.g., 1m). xlab, ylab axis labels; if ylab is missing, a label will be supplied. For the "lm" method, if xlab is missing, a label will also be supplied. a vector of selected powers to which x is to be raised. For meaningful comparipowers son of powers, 1 should be included in the vector of powers. start a constant to be added to x. If start is missing and trans is bcPower (the default) or bcnPower, then a start will be automatically generated if there are zero or negative values in x, and a warning will be printed; the auto-generated start is the absolute value of the minimum x plus 1 percent of the range of x. trans a transformation function whose first argument is a numeric vector and whose second argument is a transformation parameter, given by the powers argument; the default is bcPower, and another possibility is yjPower. bcnPower may also be used, in which case the gamma parameter is set to the value of start. arguments to be passed down.

Value

as returned by boxplot.

Tapply

Apply a Function to a Variable Within Factor Levels

Description

Applies a function, typically to compute a single statistic, like a mean, median, or standard deviation, within levels of a factor or within combinations of levels of two or more factors to produce a table of statistics. This function provides a formula interface to the standard R tapply function.

Usage

```
Tapply(formula, fun, data, na.action = na.pass, ..., targs = list())
```

Arguments

formula	a two-sided formula of the form variable ~ factor.1 + factor.2 + + factor.n or, equivalently, variable ~ factor.1*factor.2* *factor.n. The variables on the right-hand side of the formula are normally factors or are otherwise coerced to factors.
fun	a function, like mean, median, or sd, that takes a vector first argument and typically returns a single number as its value.
data	an optional data frame within which to find the variable and factor(s).
na.action	a function to handle missing values, as in statistical modeling functions like lm ; the default is na.pass.
•••	arguments to pass to the function given in the fun argument, such as (commonly) na.rm=TRUE.
targs	a list of optional arguments to pass to tapply.

testTransform 139

Details

The function given by fun is applied to the values of the left-hand-side variable in formula within (combination of) levels of the factor(s) given in the right-hand side of formula, producing a table of statistics.

Value

The object returned by tapply, typically simply printed.

Examples

testTransform

Likelihood-Ratio Tests for Univariate or Multivariate Power Transformations to Normality

Description

testTransform computes likelihood ratio tests for particular values of the power parameter based on powerTransform objects.

140 testTransform

Usage

```
testTransform(object, lambda)
## S3 method for class 'powerTransform'
testTransform(object, lambda=rep(1, dim(object$y)[2]))
## S3 method for class 'lmerModpowerTransform'
testTransform(object, lambda=1)
## S3 method for class 'bcnPowerTransformlmer'
testTransform(object, lambda=1)
```

Arguments

object An object created by a call to powerTransform.

lambda A vector of powers of length equal to the number of variables transformed.

Details

The function powerTransform is used to estimate a power transformation for a univariate or multivariate sample or multiple linear regression problem, using the method of Box and Cox (1964). It is usual to round the estimates to nearby convenient values, and this function is use to compulte a likelihood ratio test for values of the transformation parameter other than the ml-type estimate.

For one-parameter families of transformations, namely the Box-Cox power family bcPower and the Yeo-Johnson power family yjPower, this function computes a test based on twice the difference in the log-likelihood between the maximum likelihood-like estimate and the log-likelihood evaluated at the value of lambda specified.

For the bcnPower Box-Cox power with negatives allowed, the test is based on the profile loglikelihood maximizing over the location (or gamma) parameter(s). Thus, gamma is treated as a nusiance parameter.

Value

A data frame with one row giving the value of the test statistic, its degrees of freedom, and a p-value. The test is the likelihood ratio test, comparing the value of the log-likelihood at the hypothesized value to the value of the log-likelihood at the maximum likelihood estimate.

Examples

TransformationAxes

Axes for Transformed Variables

Description

These functions produce axes for the original scale of transformed variables. Typically these would appear as additional axes to the right or at the top of the plot, but if the plot is produced with axes=FALSE, then these functions could be used for axes below or to the left of the plot as well.

Usage

```
basicPowerAxis(power, base=exp(1),
    side=c("right", "above", "left", "below"),
    at, start=0, lead.digits=1, n.ticks, grid=FALSE, grid.col=gray(0.50),
    grid.lty=2,
    axis.title="Untransformed Data", cex=1, las=par("las"))
bcPowerAxis(power, side=c("right", "above", "left", "below"),
    at, start=0, lead.digits=1, n.ticks, grid=FALSE, grid.col=gray(0.50),
    grid.lty=2,
    axis.title="Untransformed Data", cex=1, las=par("las"))
bcnPowerAxis(power, shift, side=c("right", "above", "left", "below"),
    at, start=0, lead.digits=1, n.ticks, grid=FALSE, grid.col=gray(0.50),
    grid.lty=2,
    axis.title="Untransformed Data", cex=1, las=par("las"))
yjPowerAxis(power, side=c("right", "above", "left", "below"),
at, lead.digits=1, n.ticks, grid=FALSE, grid.col=gray(0.50),
  grid.lty=2,
```

142 TransformationAxes

```
axis.title="Untransformed Data", cex=1, las=par("las"))
probabilityAxis(scale=c("logit", "probit"),
side=c("right", "above", "left", "below"),
at, lead.digits=1, grid=FALSE, grid.lty=2, grid.col=gray(0.50),
    axis.title = "Probability", interval = 0.1, cex = 1, las=par("las"))
```

Arguments

power	power for Box-Cox, Box-Cox with negatives, Yeo-Johnson, or simple power transformation.
shift	the shift (gamma) parameter for the Box-Cox with negatives family.
scale	transformation used for probabilities, "logit" (the default) or "probit".
side	side at which the axis is to be drawn; numeric codes are also permitted: side = 1 for the bottom of the plot, side=2 for the left side, side = 3 for the top, side = 4 for the right side.
at	numeric vector giving location of tick marks on original scale; if missing, the function will try to pick nice locations for the ticks.
start	if a <i>start</i> was added to a variable (e.g., to make all data values positive), it can now be subtracted from the tick labels.
lead.digits	number of leading digits for determining 'nice' numbers for tick labels (default is 1.
n.ticks	number of tick marks; if missing, same as corresponding transformed axis.
grid	if TRUE grid lines for the axis will be drawn.
grid.col	color of grid lines.
grid.lty	line type for grid lines.
axis.title	title for axis.
cex	relative character expansion for axis label.
las	if \emptyset , ticks labels are drawn parallel to the axis; set to 1 for horizontal labels (see par).
base	base of log transformation for power.axis when power = 0 .
interval	desired interval between tick marks on the probability scale.

Details

The transformations corresponding to the three functions are as follows:

```
basicPowerAxis: Simple power transformation, x'=x^p for p\neq 0 and x'=\log x for p=0. bcPowerAxis: Box-Cox power transformation, x'=(x^\lambda-1)/\lambda for \lambda\neq 0 and x'=\log x for \lambda=0.
```

bcnPowerAxis: Box-Cox with negatives power transformation, the Box-Cox power transformation of $z=.5*(y+(y^2+\gamma^2)^{1/2})$, where γ is strictly positive if y includes negative values and non-negative otherwise. The value of z is always positive.

TransformationAxes 143

```
yjPowerAxis: Yeo-Johnson power transformation, for non-negative x, the Box-Cox transformation of x+1; for negative x, the Box-Cox transformation of |x|+1 with power 2-p. probabilityAxis: logit or probit transformation, logit =\log[p/(1-p)], or probit =\Phi^{-1}(p), where \Phi^{-1} is the standard-normal quantile function.
```

These functions will try to place tick marks at reasonable locations, but producing a good-looking graph sometimes requires some fiddling with the at argument.

Value

These functions are used for their side effects: to draw axes.

```

vif

vif

Variance Inflation Factors

Description

Calculates variance-inflation and generalized variance-inflation factors (VIFs and GVIFs) for linear, generalized linear, and other regression models.

Usage

```
vif(mod, ...)
## Default S3 method:
vif(mod, ...)
## S3 method for class 'merMod'
vif(mod, ...)
## S3 method for class 'polr'
vif(mod, ...)
## S3 method for class 'svyolr'
vif(mod, ...)
```

Arguments

mod for the default method, an object that responds to coef, vcov, and model.matrix, such as an lm or glm object.
... not used.

Details

If all terms in an unweighted linear model have 1 df, then the usual variance-inflation factors are calculated.

If any terms in an unweighted linear model have more than 1 df, then generalized variance-inflation factors (Fox and Monette, 1992) are calculated. These are interpretable as the inflation in size of the confidence ellipse or ellipsoid for the coefficients of the term in comparison with what would be obtained for orthogonal data.

The generalized vifs are invariant with respect to the coding of the terms in the model (as long as the subspace of the columns of the model matrix pertaining to each term is invariant). To adjust for the dimension of the confidence ellipsoid, the function also prints $GVIF^{1/(2\times df)}$ where df is the degrees of freedom associated with the term.

Through a further generalization, the implementation here is applicable as well to other sorts of models, in particular weighted linear models, generalized linear models, and mixed-effects models.

Specific methods are provided for ordinal regression model objects produced by polr in the MASS package and svyolr in the survey package, which are "intercept-less"; VIFs or GVIFs for linear and similar regression models without intercepts are generally not sensible.

wcrossprod 145

Value

A vector of vifs, or a matrix containing one row for each term in the model, and columns for the GVIF, df, and $GVIF^{1/(2\times df)}$.

wcrossprod

Weighted Matrix Crossproduct

Description

Given matrices x and y as arguments and an optional matrix or vector of weights, w, return a weighted matrix cross-product, t(x) w y. If no weights are supplied, or the weights are constant, the function uses crossprod for speed.

Usage

```
wcrossprod(x, y, w)
```

Arguments

x, y numeric matrices; missing(y) is taken to be the same matrix as x. Vectors are promoted to single-column or single-row matrices, depending on the context.

w A numeric vector or matrix of weights, conformable with x and y.

Value

A numeric matrix, with appropriate dimnames taken from x and y.

Author(s)

Michael Friendly, John Fox <jfox@mcmaster.ca>

crossprod

Examples

```
set.seed(12345)
n <- 24
drop <- 4
sex <- sample(c("M", "F"), n, replace=TRUE)</pre>
x1 <- 1:n
x2 <- sample(1:n)
extra <- c( rep(0, n - drop), floor(15 + 10 * rnorm(drop)) )
y1 <- x1 + 3*x2 + 6*(sex=="M") + floor(10 * rnorm(n)) + extra
y2 <- x1 - 2*x2 - 8*(sex=="M") + floor(10 * rnorm(n)) + extra
# assign non-zero weights to 'dropped' obs
wt <- c(rep(1, n-drop), rep(.2,drop))
X \leftarrow cbind(x1, x2)
Y \leftarrow cbind(y1, y2)
wcrossprod(X)
wcrossprod(X, w=wt)
wcrossprod(X, Y)
wcrossprod(X, Y, w=wt)
wcrossprod(x1, y1)
wcrossprod(x1, y1, w=wt)
```

whichNames

Position of Row Names

Description

These functions return the indices of the supplied row names of a data frame or names of another object, such as a vector or list. whichNames is just an alias for which.names.

Usage

```
whichNames(names, object, ...)
which.names(names, object, ...)
## S3 method for class 'data.frame'
whichNames(names, object, ...)
## Default S3 method:
whichNames(names, object, ...)
```

whichNames 147

Arguments

names a name or character vector of names.

object a data frame or an object with a names attribute.

... not used.

Value

Returns the index or indices of names in row names of the data frame or names of an object of another class.

Author(s)

```
John Fox <jfox@mcmaster.ca>
```
